[0003]   Not Applicable.

15   BACKGROUND OF THE INVENTION

[0004]   Sulfatases play a role in numerous and diverse metabolic and physiological processes in mammals. These enzymes are involved, for example, in steroid metabolism, hormonally-mediated reproductive and developmental events, and hydrolytic reactions that occur within the lysosomal compartment. The sulfatases (EC 3.1.6.) are a family of hydrolytic

20 enzymes which catalyze the reversible hydrolysis of sulfate esters. In many tissues, the extracellular matrix comprises one or more sulfated carbohydrates, sulfated polypeptides, or both. Certain lipids also comprise sulfate residues that can be cleaved by sulfatases. Sulfatases can have a role in remodeling, forming, and degrading extracellular matrix, and can affect movement or growth of cells into or through extracellular matrix.

25   [0005]   Characterized members of the sulfatase family include arylsulfatase A (EC 3.1.6.8) a lysosomal enzyme which hydrolyzes cerebroside sulfate; arylsulfatase B (EC 3.1.6.12) a lysosomal enzyme which hydrolyzes the sulfate ester group from N-acetylgalactosamine 4-sulfate residues of dermatan sulfate; steryl-sulfatase (EC 3.1.6.2) a membrane bound microsomal enzyme which hydrolyzes 3-beta-hydroxy steroid sulfates; iduronate 2-sulfatase

30 precursor (EC 3.1.6.13) a lysosomal enzyme which hydrolyzes the 2-sulfate groups from non-

reducing terminal iduronic acid residues in dermatan sulfate and heparan sulfate; N-acetylgalactosamine-6-sulfatase (EC 3.1.6.4) an enzyme which hydrolyzes the 6-sulfate groups of the N-acetyl-D-galactosamine 6-sulfate units of chondroitin sulfate and D-galactose 6-sulfate units of keratan sulfate; choline sulfatase (EC 3.1.6.6) a bacterial enzyme which converts choline-O-sulfate to choline; glucosamine-6-sulfatase (EC 3.1.6.14) a lysosomal enzyme which hydrolyzes N-acetyl-D-glucosamine 6-sulfate units of heparan sulfate and keratan sulfate; and N-sulphoglucosamine sulphohydrolase (EC 3.10.1.1) a lysosomal enzyme which catalyzes the hydrolysis of N-sulfo-d-glucosamine into glucosamine and sulfate. The sulfatases are structurally related (Peters et al., 1990, J. Biol. Chem., 265:3374-3381; Wilson et al., 1990, Proc. Natl. Acad. Sci., U.S. A., 87:8531-8535; de Hostos et al., 1989, Mol. Gen. Genet. 218:229-239).

[0006] Numerous sulfatases have been described, and many more are believed to exist. Deficiencies or abnormalities of function or expression levels of these enzymes have been implicated in disorders such as metachromatic leukodystrophy, lysosomal enzyme deficiency, arylsulfatase A pseudodeficiency, breast cancers, types II and VI mucopolysaccharidoses, sphingolipidoses, Sneddon syndrome, androgenic alopecia, Maroteaux-Lamy syndrome, and X-linked ichthyosis. In view of the widespread and critical nature of sulfatase activities in numerous normal and pathological physiological processes, a need exists for identification of further sulfatases. The present invention satisfies this need by providing a novel human sulfatase.

SUMMARY OF THE INVENTION

[0007] The present invention is based, in part, on the discovery of a novel gene encoding a sulfatase, the gene being referred to herein as "22437". The nucleotide sequence of a cDNA encoding 22437 is shown in SEQ ID NO: 1, and the amino acid sequence of a 22437 polypeptide is shown in SEQ ID NO: 2. In addition, the nucleotide sequence of the coding region is depicted in SEQ ID NO: 3.

[0008] Accordingly, in one aspect, the invention features a nucleic acid molecule that encodes a 22437 protein or polypeptide, e.g., a biologically active portion of the 22437 protein. In a preferred embodiment the isolated nucleic acid molecule encodes a polypeptide having the

amino acid sequence SEQ ID NO: 2. In other embodiments, the invention provides isolated 22437 nucleic acid molecules having the nucleotide sequence of one of SEQ ID NOs: 1 and 3.

[0009]   In still other embodiments, the invention provides nucleic acid molecules that have sequences that are substantially identical (e.g., naturally occurring allelic variants) to the nucleotide sequence of either of SEQ ID NOs: 1 and 3. In other embodiments, the invention provides a nucleic acid molecule which hybridizes under stringent hybridization conditions with a nucleic acid molecule having a sequence comprising the nucleotide sequence of either of SEQ ID NOs: 1 and 3, wherein the nucleic acid encodes a full length 22437 protein or an active fragment thereof.

[0010]   In a related aspect, the invention further provides nucleic acid constructs that include a 22437 nucleic acid molecule described herein. In certain embodiments, the nucleic acid molecules of the invention are operatively linked to native or heterologous regulatory sequences. Also included are vectors and host cells containing the 22437 nucleic acid molecules of the invention, e.g., vectors and host cells suitable for producing 22437 nucleic acid molecules and polypeptides.

[0011]   In another related aspect, the invention provides nucleic acid fragments suitable as primers or hybridization probes for detection of 22437-encoding nucleic acids.

[0012]   In still another related aspect, isolated nucleic acid molecules that are antisense to a 22437-encoding nucleic acid molecule are provided.

[0013]   In another aspect, the invention features 22437 polypeptides, and biologically active or antigenic fragments thereof that are useful, e.g., as reagents or targets in assays applicable to treatment and diagnosis of 22437-mediated or related disorders (e.g., disorders related to aberrant sulfatase activity or aberrant formation or hydrolysis of sulfate ester bonds, such as those described herein). In another embodiment, the invention provides 22437 polypeptides which are localized in the nucleus or in the nuclear membrane when expressed. Preferred polypeptides are 22437 proteins including at least one sulfatase domain, and preferably having a 22437 activity, e.g., a 22437 activity as described herein. Preferred polypeptides are 22437 proteins including at least one transmembrane domain and at least one sulfatase domain.

[0014]   In other embodiments, the invention provides 22437 polypeptides, e.g., a 22437 polypeptide having the amino acid sequence shown in SEQ ID NO: 2, an amino acid sequence

that is substantially identical to the amino acid sequence shown in SEQ ID NO: 2, or an amino acid sequence encoded by a nucleic acid molecule having a nucleotide sequence which hybridizes under stringent hybridization conditions to a nucleic acid molecule comprising the nucleotide sequence of either of SEQ ID NOs: 1 and 3, wherein the nucleic acid encodes a full length 22437 protein or an active fragment thereof.

[0015]   In a related aspect, the invention further provides nucleic acid constructs that include a 22437 nucleic acid molecule described herein.

[0016]   In a related aspect, the invention provides 22437 polypeptides or fragments operatively linked to non-22437 polypeptides to form fusion proteins.

[0017]   In another aspect, the invention features antibodies and antigen-binding fragments thereof, that react with, or more preferably, specifically bind, 22437 polypeptides.

[0018]   In another aspect, the invention provides methods of screening for compounds that modulate the expression or activity of the 22437 polypeptides or nucleic acids.

[0019]   In still another aspect, the invention provides a process for modulating 22437 polypeptide or nucleic acid expression or activity, e.g., using the screened compounds. In certain embodiments, the methods involve treatment of conditions related to aberrant activity or expression of the 22437 polypeptides or nucleic acids, such as conditions involving aberrant or deficient sulfatase activity or aberrant formation or hydrolysis of sulfate ester bonds.

[0020]   The invention also provides assays for determining the activity of or the presence or absence of 22437 polypeptides or nucleic acid molecules in a biological sample, including for disease diagnosis.

[0021]   In further aspect the invention provides assays for determining the presence or absence of a genetic alteration in a 22437 polypeptide or nucleic acid molecule, including for disease diagnosis.

[0022]   The invention includes a method of inhibiting the ability of a cell to degrade an extracellular matrix. This method comprises inhibiting the activity of 22437 protein expressed by the cell. The ability of the cell to degrade the extracellular matrix is thereby inhibited. The activity of 22437 protein can be inhibited by inhibiting expression of the 22437 gene in the cell, for example by administering to the cell an antisense oligonucleotide which hybridizes under stringent conditions with a transcript (e.g., an mRNA) of the 22437 gene, an antisense

oligonucleotide which hybridizes under stringent conditions with a polynucleotide having the nucleotide sequence SEQ ID NO: 1, or an antisense oligonucleotide which hybridizes under stringent conditions with a polynucleotide having the nucleotide sequence SEQ ID NO: 3. Alternatively, the activity of 22437 protein can be inhibited by inhibiting a catalytic activity of 22437 protein without significantly affecting 22437 gene expression in the cell. For example, the activity of 22437 can be inhibited by administering to the cell an agent which inhibits an activity of 22437 protein, such as an antibody which specifically binds with 22437 protein.

[0023]   In another aspect, the invention relates to a method for assessing whether a test compound is useful for modulating at least one phenomenon selected from the group consisting of tumor establishment, tumor growth, tumor metastasis, epithelial cell proliferation, endothelial cell proliferation, neuronal cell growth, wound healing, and cerebral injury healing. The method comprises:

a) adding the test compound to a first composition comprising a polypeptide that has an amino acid sequence at least 80% identical to SEQ ID NO: 2 and that exhibits a 22437 activity (e.g., sulfatase activity or ability to degrade an extracellular matrix) and;

b) comparing the 22437 activity in the first composition and 22437 activity in a second composition that is substantially identical to the first, except that it does not comprise the test compound.

A difference in 22437 activity in the first and second compositions is an indication that the test compound is useful for modulating the phenomenon.

[0024]   The invention also includes a method for assessing whether a test compound is useful for modulating at least one phenomenon selected from the group consisting of tumor establishment, tumor growth, tumor metastasis, epithelial cell proliferation, endothelial cell proliferation, neuronal cell growth, wound healing, and cerebral injury healing. This method comprises

a) adding the test compound to a first composition comprising a cell which comprises a nucleic acid that encodes a polypeptide that has an amino acid sequence at least 80% identical to SEQ ID NO: 2 and that exhibits a 22437 activity and;

b) comparing 22437 activity in the first composition and 22437 activity in a second composition that is substantially identical to the first composition, except that it does not comprise the test compound.

A difference in 22437 activity in the first and second compositions is an indication that the test compound is useful for modulating the phenomenon.

[0025]   The invention further relates to a method of making a pharmaceutical composition for modulating at least one phenomenon selected from the group consisting of tumor establishment, tumor growth, tumor metastasis, epithelial cell proliferation, endothelial cell proliferation, neuronal cell growth, wound healing, and cerebral injury healing. The method comprises selecting a test compound useful for modulating the phenomenon as described herein and combining the test compound with a pharmaceutically acceptable carrier in order to make the pharmaceutical composition. This composition can be used to modulate one or more of these phenomena in a human.

[0026]   The invention includes another method for identifying a compound useful for modulating at least one phenomenon selected from the group consisting of tumor establishment, tumor growth, tumor metastasis, epithelial cell proliferation, endothelial cell proliferation, neuronal cell growth, wound healing, and cerebral injury healing. This method comprises

a) contacting the test compound and a polypeptide selected from the group consisting of

i) a polypeptide which is encoded by a nucleic acid molecule comprising a portion having a nucleotide sequence which is at least 60% identical to either of SEQ ID NOs: 1 and 3; and

ii) a fragment of a polypeptide having either an amino acid sequence comprising SEQ ID NO: 2, wherein the fragment comprises at least 15 contiguous amino acid residues of SEQ ID NO: 2

or a cell that expresses the polypeptide; and

b) determining whether the polypeptide binds with the test compound.

Binding of the polypeptide and the test compound is an indication that the test compound is useful for modulating the phenomenon. For example, the polypeptide can be one which

- 6 -

exhibits an epitope in common with a polypeptide having the amino acid sequence SEQ ID NO: 2.

[0027]   Other features and advantages of the invention will be apparent from the following detailed description, and from the claims.

5

BRIEF DESCRIPTION OF THE DRAWINGS

[0028]   Figure 1 depicts a cDNA sequence (SEQ ID NO: 1) and predicted amino acid sequence (SEQ ID NO: 2) of human 22437. The methionine-initiated open reading frame of human 22437 (without the 5'- and 3'-non-translated regions) starts at nucleotide 331 of SEQ ID

10   NO: 1, and the coding region (not including the terminator codon; shown in SEQ ID NO: 3) extends through nucleotide 2940 of SEQ ID NO: 1.

[0029]   Figure 2 depicts a hydropathy plot of human 22437. Relatively hydrophobic residues are shown above the dashed horizontal line, and relative hydrophilic residues are below the dashed horizontal line. The cysteine residues (cys) are indicated by short vertical

15   lines below the hydropathy trace. The numbers corresponding to the amino acid sequence of human 22437 are indicated. Polypeptides of the invention include fragments which include: all or part of a hydrophobic sequence, i.e., a sequence above the dashed line, e.g., the sequence of about residues 350-375 of SEQ ID NO: 2; all or part of a hydrophilic sequence, i.e., a sequence below the dashed line, e.g., the sequence of about residues 95-120 or 550-580 of SEQ ID NO:

20   2; a sequence which includes a cysteine residue; or a glycosylation site.

[0030]   Figure 3, comprising Figures 3A through 3S, depicts an alignment of the nucleotide sequence of a cDNA encoding human 22437 protein described herein ("22437"; SEQ ID NO: 1) and the nucleotide sequence of a cDNA encoding human KIAA1427 ("1427"; SEQ ID NO: 11). The alignment was made using the ALIGN software available at

25   http://xyliam.igh.cnrs.fr/bin/nph-align_query.pl, using the default parameters, including gap opening penalty = 12, and gap extension penalty = 2 (Parson et al., 1997, Genomics 46:24-36).

[0031]   Figure 4, comprising Figures 4A through 4D, depicts an alignment of the amino acid sequence of human 22437 protein ("22437"; SEQ ID NO: 2) and human KIAA1427 protein ("1427"; SEQ ID NO: 12) using the same software and parameters as described in Figure 3.

30

DETAILED DESCRIPTION

[0032] The human 22437 cDNA sequence (Figure 1; SEQ ID NO: 1), which is approximately 3513 nucleotide residues long including non-translated regions, contains a predicted methionine-initiated coding sequence of about 2610 nucleotide residues, excluding termination codon (i.e., nucleotide residues 331-2940 of SEQ ID NO: 1; also shown in SEQ ID NO: 3). The coding sequence encodes an 870 amino acid residue protein having the amino acid sequence SEQ ID NO: 2.

[0033] Human 22437 contains a predicted sulfatase domain PF00884) at about amino acid residues 44 to 472 of SEQ ID NO: 2. A transmembrane domain is predicted at about amino acid residues 7 to 26 of SEQ ID NO: 2.

[0034] The human 22437 protein has predicted N-glycosylation sites (Pfam accession number PS00001) at about amino acid residues 65-68, 112-115, 132-135, 149-152, 171-174, 198-201, 241-244, 561-564, 608-611, 717-720, 754-757, and 764-767 of SEQ ID NO: 2; a predicted cAMP-/cGMP-dependent protein kinase phosphorylation site (Pfam accession number PS00004) at about amino acid residues 854-857 of SEQ ID NO: 2; predicted protein kinase C phosphorylation sites (Pfam accession number PS00005) at about amino acid residues 67-69, 97-99, 206-208, 392-394, 469-471, 536-538, 563-565, 600-602, 815-817, and 857-859 of SEQ ID NO: 2; predicted casein kinase II phosphorylation sites (Pfam accession number PS00006) located at about amino acid residues 108-111, 289-292, 368-371, 453-456, and 762-765 of SEQ ID NO: 2; predicted N-myristoylation sites (Pfam accession number PS00008) at about amino acid residues 20-25, 162-167, 184-189, 326-331, 484-489, 500-505, 552-557, 579-584, and 832-837 of SEQ ID NO: 2; a predicted amidation site (Pfam accession number PS00009) at about amino acid residues 516-519 of SEQ ID NO: 2; and a predicted sulfatase signature 1 site (Pfam accession number PS00523) at about amino acid residues 86-98 of SEQ ID NO: 2.

[0035] For general information regarding PFAM identifiers, PS prefix and PF prefix domain identification numbers, refer to Sonnhammer et al. (1997, Protein 28:405-420) and http://www.psc.edu/general/ software/packages/pfam/pfam.html.

[0036] The 22437 protein contains a significant number of structural characteristics in common with members of the sulfatase family. The term "family" when referring to the protein

and nucleic acid molecules of the invention means two or more proteins or nucleic acid molecules having a common structural domain or motif and having sufficient amino acid or nucleotide sequence homology as defined herein. Such family members can be naturally or non-naturally occurring and can be from either the same or different species. For example, a family can contain a first protein of human origin as well as other distinct proteins of human origin, or alternatively, can contain homologues of non-human origin, e.g., sulfatase proteins for any species described in the art (e.g., Peters et al., 1990, J. Biol. Chem., 265:3374-3381; Wilson et al., 1990, Proc. Natl. Acad. Sci., U.S. A., 87:8531-8535; de Hostos et al., 1989, Mol. Gen. Genet. 218:229-239 and references cited therein). Members of a family can also have common functional characteristics.

[0037] A 22437 polypeptide can include a sulfatase domain. As used herein, the term "sulfatase domain" refers to a protein domain having an amino acid sequence about 300-500 residues in length, preferably, at least about 400-500 residues, more preferably about 429 residues and has a bit score for the alignment of the sequence to the sulfatase domain (HMM) of at least 100 or greater, preferably 200 or greater, and more preferably 250 or greater. The sulfatase domain has been assigned the PFAM accession PF00884 (http://genome.wustl.edu/Pfam/html).

[0038] In a preferred embodiment, a 22437 polypeptide or protein has a sulfatase domain or a region which includes at least about 300-500, more preferably about 400-500, or 429 amino acid residues and has at least about 60%, 70%, 80%, 90%, 95%, 99%, or 100% homology with a sulfatase domain, e.g., the sulfatase domain of human 22437 (e.g., residues 44-472 of SEQ ID NO: 2).

[0039] To identify the presence of a sulfatase domain profile in a 22437 receptor, the amino acid sequence of the protein is searched against a database of HMMs (e.g., the Pfam database, release 2.1) using the default parameters (http://www.sanger.ac.uk/Software/Pfam/HMM_search). For example, the hmmsf program, which is available as part of the HMMER package of search programs, is a family specific default program for PF00884 and score of 100 is the default threshold score for determining a hit. For example, using ORFAnalyzer software, a sulfatase domain profile was identified in the amino acid sequence of SEQ ID NO: 2 (e.g., amino acids 44-472 of SEQ ID NO: 2).

Accordingly, a 22437 protein having at least about 60-70%, more preferably about 70-80%, or about 80-90% homology with the sulfatase domain profile of human 22437 is within the scope of the invention.

[0040] In one embodiment, a 22437 protein includes at least one transmembrane domain. As used herein, the term "transmembrane domain" includes an amino acid sequence of about 5 amino acid residues in length that spans the plasma membrane. More preferably, a transmembrane domain includes about at least 10, 15, 20 or 22 amino acid residues and spans a membrane. Transmembrane domains are rich in hydrophobic residues, and typically have an alpha-helical structure. In a preferred embodiment, at least 50%, 60%, 70%, 80%, 90%, or 95% or more of the amino acids of a transmembrane domain are hydrophobic, e.g., leucines, isoleucines, tyrosines, or tryptophans. Transmembrane domains are described in, for example, htto://pfam.wustl.edu/cgi-bin/getdesc?name=7tm-1, and Zagotta W.N. et al. (1996, Annu. Rev. Neurosci. 19: 235-263), the contents of which are incorporated herein by reference. Amino acid residues 7 to about 26 of SEQ ID NO: 2 comprise a transmembrane domain in a 22437 protein. In one embodiment, the amino-terminal domain of 22437 protein (i.e., about residues 1-6 of SEQ ID NO: 2) is on the cytoplasmic side of a cellular membrane (e.g., the nuclear membrane or the cytoplasmic membrane) and the carboxyl-terminal domain (i.e., about residues 27-870 of SEQ ID NO: 2) is on the non-cytoplasmic side of the same membrane. In another embodiment, the amino-terminal domain is oriented on the non-cytoplasmic side of the membrane and the carboxyl-terminal domain is oriented on the cytoplasmic side.

[0041] The transmembrane region of 22437 (i.e., the hydrophobic region at about residues 7-26 of SEQ ID NO: 2) can also function as a signal sequence, whereby this region directs a 22437 protein that comprises the region to be exported from a cell that is synthesizing the protein into the extracellular medium or the periplasmic space. The exported protein can remain attached to the cytoplasmic membrane, residues 7-26 of SEQ ID NO: 2 acting as a transmembrane region. Alternatively, the signal sequence can be cleaved at about residue 27 (i.e., on the carboxyl-terminal side of one of residues 24, 25, 26, 27, or 28) to release the 22437 protein from the cytoplasmic membrane.

[0042] 22437 protein is predicted to include several nuclear targeting sequences, including those locate at about residues 518-521, 524-528, 654-656, and 702-706 of SEQ ID NO: 2.

22437 protein is also predicted to exhibit a coiled coil conformation at about amino acid residues 615-655 of SEQ ID NO: 2. In addition, 22437 protein has a relatively high basic amino acid residue content (14.6%). These observations suggest that 22437 protein can function in the nuclear milieu (e.g., by modulating the sulfation state of a hormone, a protein, or

5 a lipid in the nuclear compartment). Thus, in one embodiment, the 22437 polypeptide described herein is a nuclear polypeptide.

[0043] In one embodiment of the invention, a 22437 polypeptide includes at least one sulfatase domain. In another embodiment, the 22437 polypeptide includes at least one sulfatase domain and at least one transmembrane domain. The 22437 molecules of the present invention

10 can further include one or more of the N-glycosylation, cAMP-/cGMP-dependent protein kinase phosphorylation, protein kinase C phosphorylation, casein kinase II phosphorylation, N-myristoylation, amidation, and sulfatase signature 1 sites described herein, and preferably comprises most or all of them.

[0044] Because the 22437 polypeptides of the invention can modulate 22437-mediated

15 activities, they can be used to develop novel diagnostic and therapeutic agents for 22437-mediated or related disorders, as described below.

[0045] As used herein, a "22437 activity," "biological activity of 22437," or "functional activity of 22437," refers to an activity exerted by a 22437 protein, polypeptide or nucleic acid molecule on, for example, a 22437-responsive cell or on a 22437 substrate (e.g., a protein

20 substrate) as determined in vivo or in vitro. In one embodiment, a 22437 activity is a direct activity, such as association with a 22437 target molecule. A "target molecule" or "binding partner" of a 22437 protein is a molecule (e.g., a protein or nucleic acid) with which the 22437 protein binds or interacts in nature. In an exemplary embodiment, such a target molecule is a 22437 receptor. A 22437 activity can also be an indirect activity, such as a cellular signaling

25 activity mediated by interaction of the 22437 protein with a 22437 receptor.

[0046] The 22437 molecules of the present invention are predicted to have similar biological activities as sulfatase family members. For example, the 22437 proteins of the present invention can have one or more of the following activities:

(1) catalyzing hydrolysis of sulfate ester bonds;

30 (2) modulating extracellular matrix structure;

- 11 -

(3) modulating degradation or resorption of extracellular matrix;

(4) modulating interaction of a cell with an extracellular matrix;

(5) modulating movement of a cell into or through an extracellular matrix;

(6) modulating the sulfation state of a hormone;

5   (7) modulating a hormonally-mediated physiological response;

(8) modulating tumor cell invasivity,

(9) modulating tumor cell metastasis;

(10) modulating neuron growth or extension;

(11) modulating synapse formation; and

10   (12) modulating expression of a gene.

Thus, 22437 molecules described herein can act as novel diagnostic targets and therapeutic agents for prognosticating, diagnosing, preventing, inhibiting, alleviating, or curing sulfatase related disorders.

[0047]   The data disclosed herein confirm expression of 22437 protein in cancer cells and 15 indicate that 22437 protein is a sulfatase which is used by tumor cells to degrade and remodel extracellular matrix in which tumor cells occur. These data indicate that 22437 protein is involved in growth, migration, and metastasis of tumor cells, at least in breast, lung, colon, and ovarian tumors. Data disclosed herein also confirm expression of 22437 protein in proliferating vascular endothelial cells. These data indicate that 22437 protein is associated with 20 angiogenesis, most likely in that 22437 allows proliferating endothelial cells to penetrate through extracellular matrix. Taken together, the data presented herein indicate that the 22437 gene and its encoded protein have a significant role in growth and metastasis of tumors. Compounds which bind with or inhibit the activity of 22437 protein and compounds which inhibit expression of the 22437 gene are therefore useful for inhibiting or preventing metastasis, 25 growth, and metastasis of tumors in humans.

[0048]   As indicated in Figure 4, 22437 protein is substantially identical to a protein designated KIAA1247 (Nagase et al., 1999, DNA Res. 6:337-345), which has been tentatively mapped to human chromosomal location 20q12-13.2. Previously recognized genetic aberrations associated with human breast cancers and oral squamous cell carcinomas have been 30 mapped to this region (Guan et al., 1994, Nat. Genet. 8(2):155-161; Kallioniemi et al., 1995,

- 12 -

Am. J. Pathol. 147(4):905-911; Imai et al., 2001, Int. J. Mol. Med. 7(1):43-47; Isola et al., 1995 Am. J. Pathol. 147:905-911). However, no gene had previously been identified as being involved in these cancers. The data presented herein indicate that aberrations in the 22437 gene caused, or at least contributed to, these cancers.

[0049] More broadly, relatively high expression of the 22437 gene in skin decubitus, ovary, prostate epithelium, HUVEC, and kidney cells indicates that 22437 protein can function in normal tissues to facilitate repair, replacement, or renewal of endothelial and epithelial tissues, presumably by remodeling or degrading extracellular matrix through or into which new endothelial or epithelial cells must move, grow, or proliferate. Thus, compounds which enhance the activity of 22437 protein or enhance expression of the 22437 gene can enhance the regenerative capacity of endothelial and epithelial tissues, and these compounds can be used to alleviate, inhibit, prevent, or reverse the effects of disorders that are characterized by damage to endothelial and epithelial cell layers. By way of example, patients afflicted with atherosclerosis exhibit blood vessel lesions which are characterized by altered endothelial cell layers, upon, within, or under which a variety of materials can accumulate. Compounds which enhance activity or expression of 22437 can enhance the rate at which damaged vascular endothelium is repaired or replaced, thereby alleviating atherosclerosis in the patient. Similarly, a variety of bacterial and viral infections can afflict endothelial and epithelial cell layers, leading to death of endothelial and epithelial cells. 22437 compounds can be used to enhance expression of the 22437 gene, activity of 22437 protein, or both, and increase the rate at which endothelial and epithelial cells proliferate and damage to the endothelial or epithelial cell layer is repaired. Compounds which inhibit activity of 22437 protein or expression of the 22437 gene can alleviate disorders characterized by hyperproliferation of endothelial or epithelial tissues. Examples of these disorders include tumors of endothelial or epithelial origin, dermal fibroses, and psoriasis.

[0050] Other activities, as described below, include the ability to modulate function, survival, morphology, proliferation and/or differentiation of cells of tissues in which 22437 molecules are expressed. Thus, the 22437 molecules can act as novel diagnostic targets and therapeutic agents for controlling disorders involving aberrant activities of these cells.

[0051]   Data presented herein indicate that the 22437 gene is expressed at a relatively high level in certain nervous system cell types. For example, relatively high expression was observed in cerebral cortex and glial cells (astrocytes). Lower, but still significant, levels of expression were also observed in hypothalamus and glioblastoma tissues. These data indicate that 22437 can be involved in interactions of brain cells with the extracellular matrix in brain and other central nervous system (CNS) tissues. Compounds which modulate expression of the 22437 gene can therefore be used to influence the ability of neural cells to move or extend through or into extracellular matrix.

[0052]   Compounds which enhance the activity of 22437 protein or expression of the gene that encodes it can be used to enhance the ability of CNS cells to form interconnections. These compounds can also be used to repopulate areas of CNS extracellular matrix that have become depopulated owing to disease, injury, or the normal aging process. For example, stroke leads to localized death of CNS cells in a brain region to which normal blood supply is inhibited or interrupted. Following a stroke, CNS cells normally do not repopulate the affected area, and neural, sensory, cognitive, and motor defects can result from the loss of brain cells. One factor that can inhibit re-population of the affected area is the relative inability of CNS cells to migrate through CNS extracellular matrix in the absence of enzymes, such as 22437 that catalyze degradation of the matrix. Enhancing expression or activity of 22437 of CNS cells increases the ability of the cells to move or extend into or through the CNS matrix. Movement of CNS cells into the affected area and reformation or repair of cell-cell interconnections which extend through the affected area can minimize or reverse the neural deficit experienced by a stroke victim. Expression, activity, or both, of 22437 can be enhanced by supplying an enhancing compound to the brain area affected by the stroke or by treating CNS cells with the enhancing compound ex vivo prior to providing the treated CNS cells to the affected area.

[0053]   The 22437 molecules can also act as novel diagnostic targets and therapeutic agents for controlling cellular proliferative disorders (e.g., hematopoietic neoplastic disorders, carcinoma, sarcoma, metastatic disorders or hematopoietic neoplastic disorders, e.g., leukemias. A metastatic tumor can arise from a multitude of primary tumor types, including but not limited to those of prostate, colon, lung, breast, ovary, brain, and liver origin. Because ability to degrade extracellular matrix is necessary for metastasis of numerous tumors, expression of the

22437 by cells in a tumor tissue is an indication that a tumor is metastatic, or is in the process of becoming metastatic. Thus, detecting activity or expression of 22437 in a patient (i.e., in either a body fluid or a tumor tissue obtained from the patient) is an indication that the patient is afflicted with a metastatic tumor or that a previously non-metastatic tumor in the patient has become metastatic.

5

[0054]   As indicated by data described herein, expression of the 22437 gene was detected in inflammatory cells which had infiltrated into tumors in certain patients. These data indicate that expression of the 22437 gene by cells of the immune system (e.g., cytotoxic T lymphocytes, natural killer cells, macrophages, mast cells, and neutrophilic and eosinophilic granulocytes) can enhance the ability of immune cells to penetrate into a solid tumor, enhancing the ability of the immune system to inhibit the tumor and mount an effective immunological response to it. Enhancing expression of the 22437 gene, activity of 22437 protein, or both, in cells of the immune system can therefore be performed in order to inhibit, prevent, or reverse tumor growth and metastasis. Because cells of the immune system can be conveniently isolated from blood, enhancement of 22437 expression or activity can be performed ex vivo, with the enhanced cells returned either to the blood stream or to the site of the tumor to be treated.

[0055]   As used herein, the terms "cancer," "hyperproliferative" and "neoplastic" refer to cells having the capacity for autonomous growth, i.e., an abnormal state or condition characterized by rapidly proliferating cell growth. Hyperproliferative and neoplastic disease states can be categorized as pathologic, i.e., characterizing or constituting a disease state, or can be categorized as non-pathologic, i.e., a deviation from normal but not associated with a disease state. The term is meant to include all types of cancerous growths or oncogenic processes, metastatic tissues or malignantly transformed cells, tissues, or organs, irrespective of histopathologic type or stage of invasiveness. "Pathologic hyperproliferative" cells occur in disease states characterized by malignant tumor growth. Examples of non-pathologic hyperproliferative cells include proliferation of cells associated with wound repair.

[0056]   The terms "cancer" or "neoplasms" include malignancies of the various organ systems, such as affecting lung, breast, thyroid, lymphoid, gastrointestinal, and genito-urinary tract, as well as adenocarcinomas which include malignancies such as most colon cancers,

renal-cell carcinoma, prostate cancer and/or testicular tumors, non-small cell carcinoma of the lung, cancer of the small intestine and cancer of the esophagus.

[0057]   The term "carcinoma" is art recognized and refers to malignancies of endothelial, epithelial or endocrine tissues including respiratory system carcinomas, gastrointestinal system carcinomas, genitourinary system carcinomas, testicular carcinomas, breast carcinomas, prostatic carcinomas, endocrine system carcinomas, and melanomas. Exemplary carcinomas include those forming from tissue of the cervix, lung, prostate, breast, head and neck, colon and ovary. The term also includes carcinosarcomas, e.g., which include malignant tumors composed of carcinomatous and sarcomatous tissues. An "adenocarcinoma" refers to a carcinoma derived from glandular tissue or in which the tumor cells form recognizable glandular structures.

[0058]   The term "sarcoma" is art recognized and refers to malignant tumors of mesenchymal derivation.

[0059]   As used herein, the term "hematopoietic neoplastic disorders" includes diseases involving hyperplastic/neoplastic cells of hematopoietic origin, e.g., arising from myeloid, lymphoid or erythroid lineages, or precursor cells thereof. The disorders can arise from poorly differentiated acute leukemias, e.g., erythroblastic leukemia and acute megakaryoblastic leukemia. Exemplary myeloid disorders include, but are not limited to, acute promyeloid leukemia, acute myelogenous leukemia and chronic myelogenous leukemia (reviewed in Vaickus, 1991, Crit. Rev. Oncol./Hemotol. 11:267-297); lymphoid malignancies include, but are not limited to acute lymphoblastic leukemia which includes B-lineage ALL and T-lineage ALL, chronic lymphocytic leukemia, prolymphocytic leukemia, hairy cell leukemia, and Waldenstrom's macroglobulinemia. Additional forms of malignant lymphomas include, but are not limited to non-Hodgkin lymphoma and variants thereof, peripheral T cell lymphomas, adult T cell leukemia/lymphoma, cutaneous T-cell lymphoma, large granular lymphocytic leukemia, Hodgkin's disease and Reed-Sternberg disease.

[0060]   The 22437 protein, fragments thereof, and derivatives and other variants of the sequence in SEQ ID NO: 2 thereof are collectively referred to as "polypeptides or proteins of the invention" or "22437 polypeptides or proteins". Nucleic acid molecules encoding such polypeptides or proteins are collectively referred to as "nucleic acids of the invention" or

"22437 nucleic acids." 22437 molecules refer to 22437 nucleic acids, polypeptides, and antibodies.

[0061]   As used herein, the term "nucleic acid molecule" includes DNA molecules (e.g., a cDNA or genomic DNA) and RNA molecules (e.g., an mRNA) and analogs of the DNA or RNA generated, e.g., by the use of nucleotide analogs. The nucleic acid molecule can be single-stranded or double-stranded, but preferably is double-stranded DNA.

[0062]   The term "isolated or purified nucleic acid molecule" includes nucleic acid molecules that are separated from other nucleic acid molecules that are present in the natural source of the nucleic acid. For example, with regards to genomic DNA, the term "isolated" includes nucleic acid molecules that are separated from the chromosome with which the genomic DNA is naturally associated. Preferably, an "isolated" nucleic acid is free of sequences that naturally flank the nucleic acid (i.e., sequences located at the 5'- and/or 3'-ends of the nucleic acid) in the genomic DNA of the organism from which the nucleic acid is derived. For example, in various embodiments, the isolated nucleic acid molecule can contain less than about 5 kilobases, 4 kilobases, 3 kilobases, 2 kilobases, 1 kilobase, 0.5 kilobase or 0.1 kilobase of 5'- and/or 3'-nucleotide sequences which naturally flank the nucleic acid molecule in genomic DNA of the cell from which the nucleic acid is derived. Moreover, an "isolated" nucleic acid molecule, such as a cDNA molecule, can be substantially free of other cellular material, or culture medium when produced by recombinant techniques, or substantially free of chemical precursors or other chemicals when chemically synthesized.

[0063]   As used herein, the term "hybridizes under stringent conditions" describes conditions for hybridization and washing. Stringent conditions are known to those skilled in the art and can be found in available references (e.g., Current Protocols in Molecular Biology, John Wiley & Sons, N.Y., 1989, 6.3.1-6.3.6). Aqueous and non-aqueous methods are described in that reference and either can be used. A preferred example of stringent hybridization conditions are hybridization in 6× sodium chloride/sodium citrate (SSC) at about 45°C, followed by one or more washes in 0.2× SSC, 0.1% (w/v) SDS at 50°C. Another example of stringent hybridization conditions are hybridization in 6× SSC at about 45°C, followed by one or more washes in 0.2× SSC, 0.1% (w/v) SDS at 55°C. A further example of stringent hybridization conditions are hybridization in 6× SSC at about 45°C, followed by one

- 17 -

or more washes in 0.2× SSC, 0.1% (w/v) SDS at 60°C. Preferably, stringent hybridization conditions are hybridization in 6× SSC at about 45°C, followed by one or more washes in 0.2× SSC, 0.1% (w/v) SDS at 65°C. Particularly preferred stringency conditions (and the conditions that should be used if the practitioner is uncertain about what conditions should be applied to

5   determine if a molecule is within a hybridization limitation of the invention) are 0.5 molar sodium phosphate, 7% (w/v) SDS at 65°C, followed by one or more washes at 0.2× SSC, 1% (w/v) SDS at 65°C. Preferably, an isolated nucleic acid molecule of the invention that hybridizes under stringent conditions to the sequence of SEQ ID NO: 1 or SEQ ID NO: 3, corresponds to a naturally-occurring nucleic acid molecule.

10 **[0064]**   As used herein, a "naturally-occurring" nucleic acid molecule refers to an RNA or DNA molecule having a nucleotide sequence that occurs in nature (e.g., encodes a natural protein).

[0065]   As used herein, the terms "gene" and "recombinant gene" refer to nucleic acid molecules which include an open reading frame encoding a 22437 protein, preferably a

15 mammalian 22437 protein, and can further include non-coding regulatory sequences and introns.

[0066]   An "isolated" or "purified" polypeptide or protein is substantially free of cellular material or other contaminating proteins from the cell or tissue source from which the protein is derived, or substantially free from chemical precursors or other chemicals when chemically

20 synthesized. In one embodiment, the language "substantially free" means preparation of 22437 protein having less than about 30%, 20%, 10% and more preferably 5% (by dry weight), of non-22437 protein (also referred to herein as a "contaminating protein"), or of chemical precursors or non-22437 chemicals. When the 22437 protein or biologically active portion thereof is recombinantly produced, it is also preferably substantially free of culture medium,

25 i.e., culture medium represents less than about 20%, more preferably less than about 10%, and most preferably less than about 5% of the volume of the protein preparation. The invention includes isolated or purified preparations of at least 0.01, 0.1, 1.0, and 10 milligrams in dry weight.

[0067]   A "non-essential" amino acid residue is a residue that can be altered from the wild-

30 type sequence of 22437 (e.g., the sequence of either of SEQ ID NOs: 1 and 3) without

abolishing or, more preferably, without substantially altering a biological activity, whereas an "essential" amino acid residue results in such a change. For example, amino acid residues that are conserved among the polypeptides of the present invention, e.g., those present in the sulfatase domain are predicted to be particularly non-amenable to alteration.

5 [0068] A "conservative amino acid substitution" is one in which the amino acid residue is replaced with an amino acid residue having a similar side chain. Families of amino acid residues having similar side chains have been defined in the art. These families include amino acids with basic side chains (e.g., lysine, arginine, histidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, 10 threonine, tyrosine, cysteine), non-polar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan), beta-branched side chains (e.g., threonine, valine, isoleucine) and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Thus, a predicted non-essential amino acid residue in a 22437 protein is preferably replaced with another amino acid residue from the same side chain family. Alternatively, in 15 another embodiment, mutations can be introduced randomly along all or part of a 22437 coding sequence, such as by saturation mutagenesis, and the resultant mutants can be screened for 22437 biological activity to identify mutants that retain activity. Following mutagenesis of either of SEQ ID NOs: 1 and 3, the encoded protein can be expressed recombinantly and the activity of the protein can be determined.

20 [0069] As used herein, a "biologically active portion" of a 22437 protein includes a fragment of a 22437 protein that participates in an interaction between a 22437 molecule and a non-22437 molecule. Biologically active portions of a 22437 protein include peptides comprising amino acid sequences sufficiently homologous to or derived from the amino acid sequence of the 22437 protein, e.g., the amino acid sequence shown in SEQ ID NO: 2, which 25 include less amino acids than the full length 22437 proteins, and exhibit at least one activity of a 22437 protein. Typically, biologically active portions comprise a domain or motif with at least one activity of the 22437 protein, e.g., a domain or motif capable of catalyzing an activity described herein, such as hydrolysis of a sulfate ester.

[0070] A biologically active portion of a 22437 protein can be a polypeptide that for 30 example, 10, 25, 50, 100, 200, 300, 400, 500, 600, 700, or 800 or more amino acids in length.

Biologically active portions of a 22437 protein can be used as targets for developing agents that modulate a 22437-mediated activity, e.g., a biological activity described herein.

[0071] Calculations of homology or sequence identity between sequences (the terms are used interchangeably herein) are performed as follows.

5   **[0072]** To determine the percent identity of two amino acid sequences, or of two nucleic acid sequences, the sequences are aligned for optimal comparison purposes (e.g., gaps can be introduced in one or both of a first and a second amino acid or nucleic acid sequence for optimal alignment and non-homologous sequences can be disregarded for comparison purposes). In a preferred embodiment, the length of a reference sequence aligned for

10   comparison purposes is at least 30%, preferably at least 40%, more preferably at least 50%, even more preferably at least 60%, and even more preferably at least 70%, 80%, 90%, 100% of the length of the reference sequence (e.g., when aligning a second sequence to the 22437 amino acid sequence of SEQ ID NO: 2, 100 amino acid residues, preferably at least 200, 300, 400, 500, 600, 700, or 800 or more amino acid residues are aligned). The amino acid residues or

15   nucleotides at corresponding amino acid positions or nucleotide positions are then compared. When a position in the first sequence is occupied by the same amino acid residue or nucleotide as the corresponding position in the second sequence, then the molecules are identical at that position (as used herein amino acid or nucleic acid "identity" is equivalent to amino acid or nucleic acid "homology"). The percent identity between the two sequences is a function of the

20   number of identical positions shared by the sequences, taking into account the number of gaps, and the length of each gap, which need to be introduced for optimal alignment of the two sequences.

[0073] The comparison of sequences and determination of percent identity between two sequences can be accomplished using a mathematical algorithm. In a preferred embodiment,

25   the percent identity between two amino acid sequences is determined using the Needleman et al. (1970, J. Mol. Biol. 48:444-453) algorithm which has been incorporated into the GAP program in the GCG software package (available at http://www.gcg.com), using either a BLOSUM 62 matrix or a PAM250 matrix, and a gap weight of 16, 14, 12, 10, 8, 6, or 4 and a length weight of 1, 2, 3, 4, 5, or 6. In yet another preferred embodiment, the percent identity

30   between two nucleotide sequences is determined using the GAP program in the GCG software

- 20 -

package (available at http://www.gcg.com), using a NWSgapdna.CMP matrix and a gap weight of 40, 50, 60, 70, or 80 and a length weight of 1, 2, 3, 4, 5, or 6. A particularly preferred set of parameters (and the one that should be used if the practitioner is uncertain about what parameters should be applied to determine if a molecule is within a sequence identity or homology limitation of the invention) are a BLOSUM 62 scoring matrix with a gap penalty of 12, a gap extend penalty of 4, and a frameshift gap penalty of 5.

[0074] The percent identity between two amino acid or nucleotide sequences can be determined using the algorithm of Meyers et al. (1989, CABIOS, 4:11-17) which has been incorporated into the ALIGN program (version 2.0), using a PAM120 weight residue table, a gap length penalty of 12 and a gap penalty of 4.

[0075] The nucleic acid and protein sequences described herein can be used as a "query sequence" to perform a search against public databases to, for example, identify other family members or related sequences. Such searches can be performed using the NBLAST and XBLAST programs (version 2.0) of Altschul, et al. (1990, J. Mol. Biol. 215:403-410). BLAST nucleotide searches can be performed with the NBLAST program, score = 100, wordlength = 12 to obtain nucleotide sequences homologous to 22437 nucleic acid molecules of the invention. BLAST protein searches can be performed with the XBLAST program, score = 50, wordlength = 3 to obtain amino acid sequences homologous to 22437 protein molecules of the invention. To obtain gapped alignments for comparison purposes, gapped BLAST can be utilized as described in Altschul et al. (1997, Nucl. Acids Res. 25:3389-3402). When using BLAST and gapped BLAST programs, the default parameters of the respective programs (e.g., XBLAST and NBLAST) can be used. See <http://www.ncbi.nlm.nih.gov>.

[0076] "Malexpression or aberrant expression," as used herein, refers to a non-wild-type pattern of gene expression, at the RNA or protein level. It includes: expression at non-wild-type levels, i.e., over- or under-expression; a pattern of expression that differs from wild-type in terms of the time or stage at which the gene is expressed, e.g., increased or decreased expression (as compared with wild-type) at a predetermined developmental period or stage; a pattern of expression that differs from wild-type in terms of decreased expression (as compared with wild-type) in a predetermined cell type or tissue type; a pattern of expression that differs from wild-type in terms of the splicing size, amino acid sequence, post-transitional

- 21 -

modification, or biological activity of the expressed polypeptide; a pattern of expression that differs from wild-type in terms of the effect of an environmental stimulus or extracellular stimulus on expression of the gene, e.g., a pattern of increased or decreased expression (as compared with wild-type) in the presence of an increase or decrease in the strength of the

5   stimulus.

[0077]   "Subject," as used herein, can refer to a mammal, e.g., a human, or to an experimental or animal or disease model. The subject can also be a non-human animal, e.g., a horse, cow, goat, or other domestic animal.

[0078]   A "purified preparation of cells," as used herein, refers to, in the case of plant or

10   animal cells, an in vitro preparation of cells and not an entire intact plant or animal. In the case of cultured cells or microbial cells, it consists of a preparation of at least 10%, and more preferably, 50% of the subject cells.

[0079]   Various aspects of the invention are described in further detail below.

15   [0080]   Isolated Nucleic Acid Molecules

[0081]   In one aspect, the invention provides, an isolated or purified, nucleic acid molecule that encodes a 22437 polypeptide described herein, e.g., a full-length 22437 protein or a fragment thereof, e.g., a biologically active portion of 22437 protein. Also included is a nucleic acid fragment suitable for use as a hybridization probe, which can be used, e.g., to a identify

20   nucleic acid molecule encoding a polypeptide of the invention, 22437 mRNA, and fragments suitable for use as primers, e.g., PCR primers for the amplification or mutation of nucleic acid molecules.

[0082]   In one embodiment, an isolated nucleic acid molecule of the invention includes the nucleotide sequence shown in SEQ ID NO: 1 or a portion thereof. In one embodiment, the

25   nucleic acid molecule includes sequences encoding the human 22437 protein (i.e., "the coding region," from nucleotides 331-2940 of SEQ ID NO: 1), as well as 5'-non-translated sequences (nucleotides 1-330 of SEQ ID NO: 1) or 3'-non-translated sequences (nucleotides 2941-3513 of SEQ ID NO: 1). Alternatively, the nucleic acid molecule can include only the coding region of SEQ ID NO: 1 (e.g., nucleotides 331-2940, corresponding to SEQ ID NO: 3) and, e.g., no

30   flanking sequences which normally accompany the subject sequence. In another embodiment,

the nucleic acid molecule encodes a sequence corresponding to the 870 amino acid residue protein of SEQ ID NO: 2.

[0083]   In another embodiment, an isolated nucleic acid molecule of the invention includes a nucleic acid molecule which is a complement of the nucleotide sequence shown in one of SEQ ID NOs: 1 and 3, and a portion of any of these sequences. In other embodiments, the nucleic acid molecule of the invention is sufficiently complementary to the nucleotide sequence shown in either of SEQ ID NOs: 1 and 3 that it can hybridize with a nucleic acid having that sequence, thereby forming a stable duplex.

[0084]   In one embodiment, an isolated nucleic acid molecule of the invention includes a nucleotide sequence which is at least about 60%, 65%, 70%, 75%, 80%, 85%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99% or more homologous to the entire length of the nucleotide sequence shown in one of SEQ ID NOs: 1 and 3, and a portion, preferably of the same length, of either of these nucleotide sequences.

[0085]   22437 Nucleic Acid Fragments

[0086]   A nucleic acid molecule of the invention can include only a portion of the nucleic acid sequence of either of SEQ ID NOs: 1 and 3. For example, such a nucleic acid molecule can include a fragment that can be used as a probe or primer or a fragment encoding a portion of a 22437 protein, e.g., an immunogenic or biologically active portion of a 22437 protein. A fragment can comprise nucleotides corresponding to residues of SEQ ID NO: 2, which encodes a sulfatase domain of human 22437. The nucleotide sequence determined from the cloning of the 22437 gene facilitates generation of probes and primers for use in identifying and/or cloning other 22437 family members, or fragments thereof, as well as 22437 homologues, or fragments thereof, from other species.

[0087]   In another embodiment, a nucleic acid includes a nucleotide sequence that includes part, or all, of the coding region and extends into either (or both) the 5'- or 3'-non-coding region. Other embodiments include a fragment that includes a nucleotide sequence encoding an amino acid fragment described herein. Nucleic acid fragments can encode a specific domain or site described herein or fragments thereof, particularly fragments thereof that are at least about 400 amino acids in length. Fragments also include nucleic acid sequences corresponding to

- 23 -

specific amino acid sequences described above or fragments thereof. Nucleic acid fragments should not to be construed as encompassing those fragments that may have been disclosed prior to the invention.

[0088]   A nucleic acid fragment can include a sequence corresponding to a domain, region, or functional site described herein. A nucleic acid fragment can also include one or more domain, region, or functional site described herein.

[0089]   22437 probes and primers are provided. Typically a probe/primer is an isolated or purified oligonucleotide. The oligonucleotide typically includes a region of nucleotide sequence that hybridizes under stringent conditions to at least about 7, 12 or 15, preferably about 20 or 25, more preferably about 30, 35, 40, 45, 50, 55, 60, 65, or 75 consecutive nucleotides of a sense or antisense sequence of either of SEQ ID NOs: 1 and 3, and a naturally occurring allelic variant or mutant of either of SEQ ID NOs: 1 and 3.

[0090]   In a preferred embodiment the nucleic acid is a probe which is at least 5 or 10, and less than 200, more preferably less than 100, or less than 50, base pairs in length. It should be identical, or differ by 1, or fewer than 5 or 10 bases, from a sequence disclosed herein. If alignment is needed for this comparison the sequences should be aligned for maximum homology. "Looped" out sequences from deletions or insertions, or mismatches, are considered differences.

[0091]   A probe or primer can be derived from the sense or anti-sense strand of a nucleic acid that encodes a sulfatase domain at about amino acid residues 44 to 472 of SEQ ID NO: 2.

[0092]   In another embodiment a set of primers is provided, e.g., primers suitable for use in a PCR, which can be used to amplify a selected region of a 22437 sequence. The primers should be at least 5, 10, or 50 base pairs in length and less than 100, or less than 200, base pairs in length. The primers should be identical, or differs by one base from a sequence disclosed herein or from a naturally occurring variant. Primers suitable for amplifying all or a portion of any of the following regions are provided: e.g., a sulfatase domain, as defined above relative to SEQ ID NO: 2.

[0093]   A nucleic acid fragment can encode an epitope bearing region of a polypeptide described herein.

- 24 -

[0094] A nucleic acid fragment encoding a "biologically active portion of a 22437 polypeptide" can be prepared by isolating a portion of the nucleotide sequence of either of SEQ ID NOs: 1 and 3, which encodes a polypeptide having a 22437 biological activity (e.g., the biological activities of the 22437 proteins that are described herein, such as sulfatase activity or

5   ability to facilitate movement or growth of a cell into or through extracellular matrix), expressing the encoded portion of the 22437 protein (e.g., by recombinant expression in vitro) and assessing the activity of the encoded portion of the 22437 protein. For example, a nucleic acid fragment encoding a biologically active portion of 22437 includes a sulfatase domain, e.g., amino acid residues 44 to 472 of SEQ ID NO: 2. A nucleic acid fragment encoding a

10   biologically active portion of a 22437 polypeptide can comprise a nucleotide sequence that is greater than 25 or more nucleotides in length.

[0095] In one embodiment, a nucleic acid includes one that has a nucleotide sequence which is greater than 200, 300, 400, 500, 600, 700, 800, 900, 1000, 1100, 1200, 1300, 1400, 1500, 2000, 2500, 3000, or 3500 or more nucleotides in length and that hybridizes under

15   stringent hybridization conditions with a nucleic acid molecule having the sequence of either of SEQ ID NOs: 1 and 3.

[0096]   22437 Nucleic Acid Variants

[0097] The invention further encompasses nucleic acid molecules having a sequence that

20   differs from the nucleotide sequence shown in either of SEQ ID NOs: 1 and 3. Such differences can be attributable to degeneracy of the genetic code (i.e., differences which result in a nucleic acid that encodes the same 22437 proteins as those encoded by the nucleotide sequence disclosed herein). In another embodiment, an isolated nucleic acid molecule of the invention encodes a protein having an amino acid sequence which differs by at least 1, but by

25   fewer than 5, 10, 20, 50, or 100, amino acid residues from SEQ ID NO: 2. If alignment is needed for this comparison the sequences should be aligned for maximum homology. "Looped" out sequences from deletions or insertions, or mismatches, are considered differences.

[0098] Nucleic acids of the inventor can be chosen for having codons, which are preferred,

30   or non-preferred, for a particular expression system. For example, the nucleic acid can be one

- 25 -

in which at least one codon, at preferably at least 10%, or 20% of the codons has been altered such that the sequence is optimized for expression in E. coli, yeast, human, insect, or CHO cells.

[0099]   Nucleic acid variants can be naturally occurring, such as allelic variants (same locus), homologs (different locus), and orthologs (different organism) or can be non-naturally occurring. Non-naturally occurring variants can be made by mutagenesis techniques, including those applied to polynucleotides, cells, or organisms. The variants can contain nucleotide substitutions, deletions, inversions and insertions. Variation can occur in either or both the coding and non-coding regions. The variations can produce both conservative and non-conservative amino acid substitutions (as compared in the encoded product).

[0100]   In a preferred embodiment, the nucleic acid has a sequence that differs from that of either of SEQ ID NOs: 1 and 3, e.g., as follows: by at least one, but by fewer than 10, 20, 30, or 40, nucleotide residues; or by at least one but by fewer than 1%, 5%, 10% or 20% of the nucleotide residues in the subject nucleic acid. If necessary for this analysis the sequences should be aligned for maximum homology. "Looped" out sequences from deletions or insertions, or mismatches, are considered differences.

[0101]   Orthologs, homologs, and allelic variants can be identified using methods known in the art. These variants comprise a nucleotide sequence encoding a polypeptide that is 50%, at least about 55%, typically at least about 70-75%, more typically at least about 80-85%, and most typically at least about 90-95% or more identical to the nucleotide sequence shown in one of SEQ ID NOs: 1 and 3, or a fragment of one of these sequences. Such nucleic acid molecules can readily be identified as being able to hybridize under stringent conditions, to the nucleotide sequence shown in one of SEQ ID NOs: 1 and 3, or a fragment of one of these sequences. Nucleic acid molecules corresponding to orthologs, homologs, and allelic variants of the 22437 cDNAs of the invention can further be isolated by mapping to the same chromosome or locus as the 22437 gene.

[0102]   Preferred variants include those that are correlated with any of the 22437 biological activities described herein, e.g., catalyzing formation of a covalent bond between an amino acid residue of a protein (e.g., a serine or threonine residue) and a phosphate moiety.

- 26 -

[0103]   Allelic variants of 22437 (e.g., human 22437) include both functional and non-functional proteins. Functional allelic variants are naturally occurring amino acid sequence variants of the 22437 protein within a population that maintain the ability to mediate any of the 22437 biological activities described herein.

5   [0104]   Functional allelic variants will typically contain only conservative substitution of one or more amino acids of SEQ ID NO: 2, or substitution, deletion or insertion of non-critical residues in non-critical regions of the protein. Non-functional allelic variants are naturally-occurring amino acid sequence variants of the 22437 (e.g., human 22437) protein within a population that do not have the ability to mediate any of the 22437 biological activities

10   described herein. Non-functional allelic variants will typically contain a non-conservative substitution, a deletion, or insertion, or premature truncation of the amino acid sequence of SEQ ID NO: 2, or a substitution, insertion, or deletion in critical residues or critical regions of the protein.

[0105]   Moreover, nucleic acid molecules encoding other 22437 family members and, thus,

15   which have a nucleotide sequence which differs from the 22437 sequences of either of SEQ ID NOs: 1 and 3 are within the scope of the invention.

[0106]   Antisense Nucleic Acid Molecules, Ribozymes and Modified 22437 Nucleic Acid Molecules

20   [0107]   In another aspect, the invention features, an isolated nucleic acid molecule that is antisense to 22437. An "antisense" nucleic acid can include a nucleotide sequence that is complementary to a "sense" nucleic acid encoding a protein, e.g., complementary to the coding strand of a double-stranded cDNA molecule or complementary to an mRNA sequence. The antisense nucleic acid can be complementary to an entire 22437 coding strand, or to only a

25   portion thereof (e.g., the coding region of human 22437 corresponding to SEQ ID NO: 3). In another embodiment, the antisense nucleic acid molecule is antisense to a "non-coding region" of the coding strand of a nucleotide sequence encoding 22437 (e.g., the 5'- and 3'-non-translated regions).

[0108]   An antisense nucleic acid can be designed such that it is complementary to the entire

30   coding region of 22437 mRNA, but more preferably is an oligonucleotide that is antisense to

- 27 -

only a portion of the coding or non-coding region of 22437 mRNA. For example, the antisense oligonucleotide can be complementary to the region surrounding the translation start site of 22437 mRNA, e.g., between the -10 and +10 regions of the target gene nucleotide sequence of interest. An antisense oligonucleotide can be, for example, about 7, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, or 80 or more nucleotide residues in length.

[0109]   An antisense nucleic acid of the invention can be constructed using chemical synthesis and enzymatic ligation reactions using procedures known in the art. For example, an antisense nucleic acid (e.g., an antisense oligonucleotide) can be chemically synthesized using naturally occurring nucleotides or variously modified nucleotides designed to increase the biological stability of the molecules or to increase the physical stability of the duplex formed between the antisense and sense nucleic acids, e.g., phosphorothioate derivatives and acridine substituted nucleotides can be used. The antisense nucleic acid also can be produced biologically using an expression vector into which a nucleic acid has been sub-cloned in an antisense orientation (i.e., RNA transcribed from the inserted nucleic acid will be of an antisense orientation to a target nucleic acid of interest, described further in the following subsection).

[0110]   The antisense nucleic acid molecules of the invention are typically administered to a subject (e.g., by direct injection at a tissue site), or generated in situ such that they hybridize with or bind to cellular mRNA and/or genomic DNA encoding a 22437 protein to thereby inhibit expression of the protein, e.g., by inhibiting transcription and/or translation. Alternatively, antisense nucleic acid molecules can be modified to target selected cells and then administered systemically. For systemic administration, antisense molecules can be modified such that they specifically bind to receptors or antigens expressed on a selected cell surface, e.g., by linking the antisense nucleic acid molecules to peptides or antibodies that bind to cell surface receptors or antigens. The antisense nucleic acid molecules can also be delivered to cells using the vectors described herein. To achieve sufficient intracellular concentrations of the antisense molecules, vector constructs in which the antisense nucleic acid molecule is placed under the control of a strong pol II or pol III promoter are preferred.

[0111]   In yet another embodiment, the antisense nucleic acid molecule of the invention is an alpha-anomeric nucleic acid molecule. An alpha-anomeric nucleic acid molecule forms

specific double-stranded hybrids with complementary RNA in which, contrary to the usual beta-units, the strands run parallel to each other (Gaultier et al., 1987, Nucl. Acids. Res. 15:6625-6641). The antisense nucleic acid molecule can also comprise a 2'-o-methylribonucleotide (Inoue et al., 1987, Nucl. Acids Res. 15:6131-6148) or a chimeric RNA-

5   DNA analogue (Inoue et al., 1987, FEBS Lett. 215:327-330).

[0112]   In still another embodiment, an antisense nucleic acid of the invention is a ribozyme. A ribozyme having specificity for a 22437-encoding nucleic acid can include one or more sequences complementary to the nucleotide sequence of a 22437 cDNA disclosed herein (i.e., SEQ ID NO: 1 or SEQ ID NO: 3), and a sequence having known catalytic sequence responsible

10   for mRNA cleavage (see, for example, U.S. Patent number 5,093,246 or Haselhoff et al. (1988, Nature 334:585-591). For example, a derivative of a Tetrahymena L-19 IVS RNA can be constructed in which the nucleotide sequence of the active site is complementary to the nucleotide sequence to be cleaved in a 22437-encoding mRNA (e.g., U.S. Patent number 4,987,071; and U.S. Patent number 5,116,742). Alternatively, 22437 mRNA can be used to

15   select a catalytic RNA having a specific ribonuclease activity from a pool of RNA molecules (e.g., Bartel et al., 1993, Science 261:1411-1418).

[0113]   22437 gene expression can be inhibited by targeting nucleotide sequences complementary to the regulatory region of the 22437 (e.g., the 22437 promoter and/or enhancers) to form triple helical structures that prevent transcription of the 22437 gene in target

20   cells (Helene, 1991, Anticancer Drug Des. 6:569-584; Helene, et al., 1992, Ann. N.Y. Acad. Sci. 660:27-36; Maher, 1992, Bioassays 14:807-815). The potential sequences that can be targeted for triple helix formation can be increased by creating a so-called "switchback" nucleic acid molecule. Switchback molecules are synthesized in an alternating 5' to 3', 3' to 5' manner, such that they hybridize with first one strand of a duplex and then the other, eliminating the

25   necessity for a sizeable stretch of either purines or pyrimidines to be present on one strand of a duplex.

[0114]   The invention also provides detectably labeled oligonucleotide primer and probe molecules. Typically, such labels are chemiluminescent, fluorescent, radioactive, or colorimetric.

[0115] A 22437 nucleic acid molecule can be modified at the base moiety, sugar moiety or phosphate backbone to improve, e.g., the stability, hybridization, or solubility of the molecule. For example, the deoxyribose phosphate backbone of the nucleic acid molecules can be modified to generate peptide nucleic acids (Hyrup et al., 1996, Bioorg. Med. Chem. 4:5-23).

As used herein, the terms "peptide nucleic acid" (PNA) refers to a nucleic acid mimic, e.g., a DNA mimic, in which the deoxyribose phosphate backbone is replaced by a pseudopeptide backbone and only the four natural nucleobases are retained. The neutral backbone of a PNA can allow for specific hybridization to DNA and RNA under conditions of low ionic strength. The synthesis of PNA oligomers can be performed using standard solid phase peptide synthesis protocols as described in Hyrup et al. (1996, supra; Perry-O'Keefe et al., Proc. Natl. Acad. Sci. USA 93:14670-14675).

[0116] PNAs of 22437 nucleic acid molecules can be used in therapeutic and diagnostic applications. For example, PNAs can be used as antisense or anti-gene agents for sequence-specific modulation of gene expression by, for example, inducing transcription or translation arrest or inhibiting replication. PNAs of 22437 nucleic acid molecules can also be used in the analysis of single base pair mutations in a gene, (e.g., by PNA-directed PCR clamping); as 'artificial restriction enzymes' when used in combination with other enzymes, (e.g., S1 nucleases, as described in Hyrup et al., 1996, supra); or as probes or primers for DNA sequencing or hybridization (Hyrup et al., 1996, supra; Perry-O'Keefe, supra).

[0117] In other embodiments, the oligonucleotide can include other appended groups such as peptides (e.g., for targeting host cell receptors in vivo), or agents facilitating transport across the cell membrane (e.g., Letsinger et al., 1989, Proc. Natl. Acad. Sci. USA 86:6553-6556; Lemaitre et al., 1987, Proc. Natl. Acad. Sci. USA 84:648-652; PCT publication number WO 88/09810) or the blood-brain barrier (see, e.g., PCT publication number WO 89/10134). In addition, oligonucleotides can be modified with hybridization-triggered cleavage agents (e.g., Krol et al., 1988, Bio-Techniques 6:958-976) or intercalating agents (e.g., Zon, 1988, Pharm. Res. 5:539-549). To this end, the oligonucleotide can be conjugated to another molecule, (e.g., a peptide, hybridization triggered cross-linking agent, transport agent, or hybridization-triggered cleavage agent).

[0118] The invention also includes molecular beacon oligonucleotide primer and probe molecules having at least one region which is complementary to a 22437 nucleic acid of the invention, two complementary regions, one having a fluorophore and the other having a quencher, such that the molecular beacon is useful for quantitating the presence of the 22437 nucleic acid of the invention in a sample. Molecular beacon nucleic acids are described, for example, in U.S. Patent number. 5,854,033, U.S. Patent number 5,866,336, and U.S. Patent number 5,876,930.

[0119] Isolated 22437 Polypeptides

[0120] In another aspect, the invention features, an isolated 22437 protein, or fragment, e.g., a biologically active portion, for use as immunogens or antigens to raise or test (or more generally to bind) anti-22437 antibodies. 22437 protein can be isolated from cells or tissue sources using standard protein purification techniques. 22437 protein or fragments thereof can be produced by recombinant DNA techniques or synthesized chemically.

[0121] Polypeptides of the invention include those that arise as a result of the existence of multiple genes, alternative transcription events, alternative RNA splicing events, and alternative translational and post-translational events. The polypeptide can be expressed in systems, e.g., cultured cells, which result in substantially the same post-translational modifications present when the polypeptide is expressed in a native cell, or in systems which result in the alteration or omission of post-translational modifications, e.g., glycosylation or cleavage, present when expressed in a native cell.

[0122] In a preferred embodiment, a 22437 polypeptide has one or more of the following characteristics:

(1) it catalyzes hydrolysis of sulfate ester bonds;

(2) it modulates extracellular matrix structure;

(3) it modulates degradation or resorption of extracellular matrix;

(4) it modulates interaction of a cell with an extracellular matrix;

(5) it modulates movement of a cell into or through an extracellular matrix;

(6) it modulates the sulfation state of a hormone;

(7) it modulates a hormonally-mediated physiological response;

- 31 -

(8) it modulates tumor cell invasivity,

(9) it modulates tumor cell metastasis;

(10) it modulates neuron growth or extension;

(11) it modulates synapse formation;

(12) it modulates expression of a gene;

(13) it has a molecular weight, amino acid composition or other physical characteristic of a 22437 protein of SEQ ID NO: 2;

(14) it has an overall sequence similarity (identity) of at least 60-65%, preferably at least 70%, more preferably at least 75, 80, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, or 99% or more, with a portion of SEQ ID NO: 2;

(15) it has a transmembrane domain which is preferably about 70%, 80%, 90%, 95%, 96%, 97%, 98%, or 99% or more, identical with amino acid residues 7 to 26 of SEQ ID NO: 2;

(16) it has at least one non-transmembrane domain which is preferably about 70%, 80%, 90%, 95%, 96%, 97%, 98%, or 99% or more, identical with amino acid residues 27-870 of SEQ ID NO: 2; or

(17) it has a sulfatase domain which is preferably about 70%, 80%, 90%, 95%, 96%, 97%, 98%, 99% or higher, identical with amino acid residues 44-472 of SEQ ID NO: 2.

[0123]   In a preferred embodiment, the 22437 protein or fragment thereof differs only insubstantially, if at all, from the corresponding sequence in SEQ ID NO: 2. In one embodiment, it differs by at least one, but by fewer than 15, 10 or 5 amino acid residues. In another, it differs from the corresponding sequence in SEQ ID NO: 2 by at least one residue but fewer than 20%, 15%, 10% or 5% of the residues differ from the corresponding sequence in SEQ ID NO: 2 (if this comparison requires alignment the sequences should be aligned for maximum homology. "Looped" out sequences from deletions or insertions, or mismatches, are considered differences). The differences are, preferably, differences or changes at a non-essential amino acid residues or involve a conservative substitution of one residue for another. In a preferred embodiment the differences are not in residues 44 to 472 of SEQ ID NO: 2.

- 32 -

[0124] Other embodiments include a protein that has one or more changes in amino acid sequence, relative to SEQ ID NO: 2 (e.g., a change in an amino acid residue which is not essential for activity). Such 22437 proteins differ in amino acid sequence from SEQ ID NO: 2, yet retain biological activity.

[0125] In one embodiment, the protein includes an amino acid sequence at least about 60%, 65%, 70%, 75%, 80%, 85%, 90%, 95%, 98% or more homologous to SEQ ID NO: 2.

[0126] A 22437 protein or fragment is provided which has an amino acid sequence which varies from SEQ ID NO: 2 in one or both of the regions corresponding to residues 1-43 and 473-870 of SEQ ID NO: 2 by at least one, but by fewer than 15, 10 or 5 amino acid residues, but which does not differ from SEQ ID NO: 2 in the region corresponding to residues 44-472 of SEQ ID NO: 2 (if this comparison requires alignment the sequences should be aligned for maximum homology. "Looped" out sequences from deletions or insertions, or mismatches, are considered differences). In some embodiments the difference is at a non-essential residue or is a conservative substitution, while in others the difference is at an essential residue or is a non-conservative substitution.

[0127] A biologically active portion of a 22437 protein should include at least the 22437 sulfatase domain. Moreover, other biologically active portions, in which other regions of the protein are deleted, can be prepared by recombinant techniques and evaluated for one or more of the functional activities of a native 22437 protein.

[0128] In a preferred embodiment, the 22437 protein has the amino acid sequence SEQ ID NO: 2. In other embodiments, the 22437 protein is substantially identical to SEQ ID NO: 2. In yet another embodiment, the 22437 protein is substantially identical to SEQ ID NO: 2 and retains the functional activity of the protein of SEQ ID NO: 2.

[0129] 22437 Chimeric or Fusion Proteins

[0130] In another aspect, the invention provides 22437 chimeric or fusion proteins. As used herein, a 22437 "chimeric protein" or "fusion protein" includes a 22437 polypeptide linked to a non-22437 polypeptide. A "non-22437 polypeptide" refers to a polypeptide having an amino acid sequence corresponding to a protein which is not substantially homologous to the 22437 protein, e.g., a protein which is different from the 22437 protein and which is derived

- 33 -

from the same or a different organism. The 22437 polypeptide of the fusion protein can correspond to all or a portion e.g., a fragment described herein of a 22437 amino acid sequence. In a preferred embodiment, a 22437 fusion protein includes at least one or more biologically active portions of a 22437 protein. The non-22437 polypeptide can be fused to the amino or carboxyl terminus of the 22437 polypeptide.

[0131] The fusion protein can include a moiety that has a high affinity for a ligand. For example, the fusion protein can be a GST-22437 fusion protein in which the 22437 sequences are fused to the carboxyl terminus of the GST sequences. Such fusion proteins can facilitate purification of recombinant 22437. Alternatively, the fusion protein can be a 22437 protein containing a heterologous signal sequence at its amino terminus. In certain host cells (e.g., mammalian host cells), expression and/or secretion of 22437 can be increased through use of a heterologous signal sequence.

[0132] Fusion proteins can include all or a part of a serum protein, e.g., an IgG constant region, or human serum albumin.

[0133] The 22437 fusion proteins of the invention can be incorporated into pharmaceutical compositions and administered to a subject in vivo. The 22437 fusion proteins can be used to affect the bioavailability of a 22437 substrate. 22437 fusion proteins can be useful therapeutically for the treatment of disorders caused by, for example, (i) aberrant modification or mutation of a gene encoding a 22437 protein; (ii) mis-regulation of the 22437 gene; and (iii) aberrant post-translational modification of a 22437 protein.

[0134] Moreover, the 22437-fusion proteins of the invention can be used as immunogens to produce anti-22437 antibodies in a subject, to purify 22437 ligands and in screening assays to identify molecules that inhibit the interaction of 22437 with a 22437 substrate.

[0135] Expression vectors are commercially available that already encode a fusion moiety (e.g., a GST polypeptide). A 22437-encoding nucleic acid can be cloned into such an expression vector such that the fusion moiety is linked in-frame to the 22437 protein.

[0136] Variants of 22437 Proteins

[0137] In another aspect, the invention also features a variant of a 22437 polypeptide, e.g., which functions as an agonist (mimetics) or as an antagonist. Variants of the 22437 proteins

- 34 -

can be generated by mutagenesis, e.g., discrete point mutation, the insertion or deletion of sequences or the truncation of a 22437 protein. An agonist of the 22437 proteins can retain substantially the same, or a subset, of the biological activities of the naturally occurring form of a 22437 protein. An antagonist of a 22437 protein can inhibit one or more of the activities of the naturally occurring form of the 22437 protein by, for example, competitively modulating a 22437-mediated activity of a 22437 protein. Thus, specific biological effects can be elicited by treatment with a variant of limited function. Preferably, treatment of a subject with a variant having a subset of the biological activities of the naturally occurring form of the protein has fewer side effects in a subject relative to treatment with the naturally occurring form of the 22437 protein.

[0138]   Variants of a 22437 protein can be identified by screening combinatorial libraries of mutants, e.g., truncation mutants, of a 22437 protein for agonist or antagonist activity.

[0139]   Libraries of fragments e.g., amino-terminal, carboxyl-terminal, or internal fragments, of a 22437 protein coding sequence can be used to generate a variegated population of fragments for screening and subsequent selection of variants of a 22437 protein.

[0140]   Variants in which a cysteine residue is added or deleted or in which a residue that is glycosylated is added or deleted are particularly preferred.

[0141]   Methods for screening gene products of combinatorial libraries made by point mutations or truncation, and for screening cDNA libraries for gene products having a selected property. Recursive ensemble mutagenesis (REM), a technique which enhances the frequency of functional mutants in the libraries, can be used in combination with the screening assays to identify 22437 variants (Arkin et al., 1992, Proc. Natl. Acad. Sci. USA 89:7811-7815; Delgrave et al., 1993, Protein Engr. 6:327-331).

[0142]   Cell based assays can be exploited to analyze a variegated 22437 library. For example, a library of expression vectors can be transfected into a cell line, e.g., a cell line, which ordinarily responds to 22437 in a substrate-dependent manner. The transfected cells are then contacted with 22437 and the effect of the expression of the mutant on signaling by the 22437 substrate can be detected, e.g., by measuring changes in cell growth and/or enzymatic activity. Plasmid DNA can then be recovered from the cells that score for inhibition, or

- 35 -

alternatively, potentiation of signaling by the 22437 substrate, and the individual clones further characterized.

[0143] In another aspect, the invention features a method of making a 22437 polypeptide, e.g., a peptide having a non-wild-type activity, e.g., an antagonist, agonist, or super agonist of a naturally-occurring 22437 polypeptide, e.g., a naturally-occurring 22437 polypeptide. The method includes: altering the sequence of a 22437 polypeptide, e.g., altering the sequence, e.g., by substitution or deletion of one or more residues of a non-conserved region, a domain or residue disclosed herein, and testing the altered polypeptide for the desired activity.

[0144] In another aspect, the invention features a method of making a fragment or analog of a 22437 polypeptide a biological activity of a naturally occurring 22437 polypeptide. The method includes: altering the sequence, e.g., by substitution or deletion of one or more residues, of a 22437 polypeptide, e.g., altering the sequence of a non-conserved region, or a domain or residue described herein, and testing the altered polypeptide for the desired activity.

[0145] Anti-22437 Antibodies

[0146] In another aspect, the invention provides an anti-22437 antibody. The term "antibody" as used herein refers to an immunoglobulin molecule or immunologically active portion thereof, i.e., an antigen-binding portion. Examples of immunologically active portions of immunoglobulin molecules include F(ab) and F(ab')$_2$ fragments which can be generated by treating the antibody with an enzyme such as pepsin.

[0147] The antibody can be a polyclonal, monoclonal, recombinant, e.g., a chimeric or humanized, fully-human, non-human, e.g., murine, or single chain antibody. In a preferred embodiment, it has effector function and can fix complement. The antibody can be coupled to a toxin or imaging agent.

[0148] A full-length 22437 protein or, antigenic peptide fragment of 22437 can be used as an immunogen or can be used to identify anti-22437 antibodies made with other immunogens, e.g., cells, membrane preparations, and the like. The antigenic peptide of 22437 should include at least 8 amino acid residues of the amino acid sequence shown in SEQ ID NO: 2 and encompasses an epitope of 22437. Preferably, the antigenic peptide includes at least 10 amino

- 36 -

acid residues, more preferably at least 15 amino acid residues, even more preferably at least 20 amino acid residues, and most preferably at least 30 amino acid residues.

[0149]   Fragments of 22437 which include about residues 350-375 of SEQ ID NO: 2 can be used to make antibodies, e.g., for use as immunogens or to characterize the specificity of an antibody, against hydrophobic regions of the 22437 protein. Similarly, a fragment of 22437 which include about residues 95-120 or 550-580 of SEQ ID NO: 2 can be used to make an antibody against a hydrophilic region of the 22437 protein.

[0150]   Antibodies reactive with, or specific for, any of these regions, or other regions or domains described herein are provided.

[0151]   Preferred epitopes encompassed by the antigenic peptide are regions of 22437 are located on the surface of the protein, e.g., hydrophilic regions, as well as regions with high antigenicity. For example, an Emini surface probability analysis of the human 22437 protein sequence can be used to indicate the regions that have a particularly high probability of being localized to the surface of the 22437 protein and are thus likely to constitute surface residues useful for targeting antibody production.

[0152]   In a preferred embodiment the antibody binds an epitope on any domain or region on 22437 proteins described herein.

[0153]   Chimeric, humanized, but most preferably, completely human antibodies are desirable for applications which include repeated administration, e.g., therapeutic treatment (and some diagnostic applications) of human patients.

[0154]   The anti-22437 antibody can be a single chain antibody. A single-chain antibody (scFV) can be engineered (e.g., Colcher et al., 1999, Ann. N.Y. Acad. Sci. 880:263-280; Reiter, 1996, Clin. Cancer Res. 2:245-252). The single chain antibody can be dimerized or multimerized to generate multivalent antibodies having specificities for different epitopes of the same target 22437 protein.

[0155]   In a preferred embodiment, the antibody has reduced or no ability to bind an Fc receptor. For example, it can be an isotype, subtype, fragment or other mutant, which does not support binding to an Fc receptor, e.g., it can have a mutated or deleted Fc receptor binding region.

[0156] An anti-22437 antibody (e.g., monoclonal antibody) can be used to isolate 22437 by standard techniques, such as affinity chromatography or immunoprecipitation. Moreover, an anti-22437 antibody can be used to detect 22437 protein (e.g., in a cellular lysate or cell supernatant) in order to evaluate the abundance and pattern of expression of the protein. Anti-22437 antibodies can be used diagnostically to monitor protein levels in tissue as part of a clinical testing procedure, e.g., to, for example, determine the efficacy of a given treatment regimen. Detection can be facilitated by coupling (i.e., physically linking) the antibody to a detectable substance (i.e., antibody labeling). Examples of detectable substances include various enzymes, prosthetic groups, fluorescent materials, luminescent materials, bioluminescent materials, and radioactive materials. Examples of suitable enzymes include horseradish peroxidase, alkaline phosphatase, beta-galactosidase, or acetylcholinesterase; examples of suitable prosthetic group complexes include streptavidin/biotin and avidin/biotin; examples of suitable fluorescent materials include umbelliferone, fluorescein, fluorescein isothiocyanate, rhodamine, dichlorotriazinylamine fluorescein, dansyl chloride or phycoerythrin; an example of a luminescent material includes luminol; examples of bioluminescent materials include luciferase, luciferin, and aequorin, and examples of suitable radioactive material include ^{125}I, ^{131}I, ^{35}S or ^{3}H.

[0157] Recombinant Expression Vectors, Host Cells and Genetically Engineered Cells

[0158] In another aspect, the invention includes, vectors, preferably expression vectors, containing a nucleic acid encoding a polypeptide described herein. As used herein, the term "vector" refers to a nucleic acid molecule capable of transporting another nucleic acid to which it has been linked and can include a plasmid, cosmid or viral vector. The vector can be capable of autonomous replication or it can integrate into a host DNA. Viral vectors include, e.g., replication defective retroviruses, adenoviruses and adeno-associated viruses.

[0159] A vector can include a 22437 nucleic acid in a form suitable for expression of the nucleic acid in a host cell. Preferably the recombinant expression vector includes one or more regulatory sequences operatively linked to the nucleic acid sequence to be expressed. The term "regulatory sequence" includes promoters, enhancers and other expression control elements (e.g., polyadenylation signals). Regulatory sequences include those that direct constitutive

- 38 -

expression of a nucleotide sequence, as well as tissue-specific regulatory and/or inducible sequences. The design of the expression vector can depend on such factors as the choice of the host cell to be transformed, the level of expression of protein desired, and the like. The expression vectors of the invention can be introduced into host cells to thereby produce proteins

5   or polypeptides, including fusion proteins or polypeptides, encoded by nucleic acids as described herein (e.g., 22437 proteins, mutant forms of 22437 proteins, fusion proteins, and the like).

[0160]   The recombinant expression vectors of the invention can be designed for expression of 22437 proteins in prokaryotic or eukaryotic cells. For example, polypeptides of the

10   invention can be expressed in E. coli, insect cells (e.g., using baculovirus expression vectors), yeast cells or mammalian cells. Suitable host cells are discussed further in Goeddel (1990, Gene Expression Technology: Methods in Enzymology 185, Academic Press, San Diego). Alternatively, the recombinant expression vector can be transcribed and translated in vitro, for example using T7 promoter regulatory sequences and T7 polymerase.

15   [0161]   Expression of proteins in prokaryotes is most often carried out in E. coli with vectors containing constitutive or inducible promoters directing the expression of either fusion or non-fusion proteins. Fusion vectors add a number of amino acids to a protein encoded therein, usually to the amino terminus of the recombinant protein. Such fusion vectors typically serve three purposes: 1) to increase expression of recombinant protein; 2) to increase the

20   solubility of the recombinant protein; and 3) to aid in the purification of the recombinant protein by acting as a ligand in affinity purification. Often, a proteolytic cleavage site is introduced at the junction of the fusion moiety and the recombinant protein to enable separation of the recombinant protein from the fusion moiety subsequent to purification of the fusion protein. Such enzymes, and their cognate recognition sequences, include Factor Xa, thrombin

25   and enterokinase. Typical fusion expression vectors include pGEX (Pharmacia Biotech Inc; Smith et al., 1988, Gene 67:31-40), pMAL (New England Biolabs, Beverly, MA) and pRIT5 (Pharmacia, Piscataway, NJ) which fuse glutathione S-transferase (GST), maltose E binding protein, or protein A, respectively, to the target recombinant protein.

[0162]   Purified fusion proteins can be used in 22437 activity assays, (e.g., direct assays or

30   competitive assays described in detail below), or to generate antibodies specific for 22437

proteins. In a preferred embodiment, a fusion protein expressed in a retroviral expression vector of the present invention can be used to infect bone marrow cells that are subsequently transplanted into irradiated recipients. The pathology of the subject recipient is then examined after sufficient time has passed (e.g., six weeks).

[0163]   To maximize recombinant protein expression in E. coli, the protein is expressed in a host bacterial strain with an impaired capacity to proteolytically cleave the recombinant protein (Gottesman, 1990, Gene Expression Technology: Methods in Enzymology 185, Academic Press, San Diego, 119-128). Another strategy is to alter the nucleic acid sequence of the nucleic acid to be inserted into an expression vector so that the individual codons for each amino acid are those preferentially utilized in E. coli (Wada et al., 1992, Nucl. Acids Res. 20:2111-2118). Such alteration of nucleic acid sequences of the invention can be carried out by standard DNA synthesis techniques.

[0164]   The 22437 expression vector can be a yeast expression vector, a vector for expression in insect cells, e.g., a baculovirus expression vector, or a vector suitable for expression in mammalian cells.

[0165]   When used in mammalian cells, the expression vector's control functions are often provided by viral regulatory elements. For example, commonly used viral promoters are derived from polyoma, adenovirus 2, cytomegalovirus and simian virus 40 (SV40).

[0166]   In another embodiment, the recombinant mammalian expression vector is capable of directing expression of the nucleic acid preferentially in a particular cell type (e.g., tissue-specific regulatory elements are used to express the nucleic acid). Non-limiting examples of suitable tissue-specific promoters include the albumin promoter (liver-specific; Pinkert et al., 1987, Genes Dev. 1:268-277), lymphoid-specific promoters (Calame et al., 1988, Adv. Immunol. 43:235-275), in particular promoters of T cell receptors (Winoto et al., 1989, EMBO J. 8:729-733) and immunoglobulins (Banerji et al., 1983, Cell 33:729-740; Queen et al., 1983, Cell 33:741-748), neuron-specific promoters (e.g., the neurofilament promoter; Byrne et al., 1989, Proc. Natl. Acad. Sci. USA 86:5473-5477), pancreas-specific promoters (Edlund et al., 1985, Science 230:912-916), and mammary gland-specific promoters (e.g., milk whey promoter; U.S. Patent number 4,873,316 and European Patent Application publication number 264,166). Developmentally-regulated promoters are also encompassed, for example, the

murine hox promoters (Kessel et al., 1990, Science 249:374-379) and the alpha-fetoprotein promoter (Campes et al., 1989, Genes Dev. 3:537-546).

[0167]   The invention further provides a recombinant expression vector comprising a DNA molecule of the invention cloned into the expression vector in an antisense orientation. Regulatory sequences (e.g., viral promoters and/or enhancers) operatively linked to a nucleic acid cloned in the antisense orientation can be chosen which direct the constitutive, tissue specific or cell type specific expression of antisense RNA in a variety of cell types. The antisense expression vector can be in the form of a recombinant plasmid, phagemid or attenuated virus. For a discussion of the regulation of gene expression using antisense genes, see Weintraub, H. et al. (1986, Trends Genet. 1:Review).

[0168]   Another aspect the invention provides a host cell which includes a nucleic acid molecule described herein, e.g., a 22437 nucleic acid molecule within a recombinant expression vector or a 22437 nucleic acid molecule containing sequences which allow it to homologously recombine into a specific site of the host cell's genome. The terms "host cell" and "recombinant host cell" are used interchangeably herein. Such terms refer not only to the particular subject cell, but also to the progeny or potential progeny of such a cell. Because certain modifications can occur in succeeding generations due to either mutation or environmental influences, such progeny may not, in fact, be identical to the parent cell, but are included within the scope of the term as used herein.

[0169]   A host cell can be any prokaryotic or eukaryotic cell. For example, a 22437 protein can be expressed in bacterial cells such as E. coli, insect cells, yeast or mammalian cells (such as Chinese hamster ovary (CHO) cells) or COS cells. Other suitable host cells are known to those skilled in the art.

[0170]   Vector DNA can be introduced into host cells via conventional transformation or transfection techniques. As used herein, the terms "transformation" and "transfection" are intended to refer to a variety of art-recognized techniques for introducing foreign nucleic acid (e.g., DNA) into a host cell, including calcium phosphate or calcium chloride co-precipitation, DEAE-dextran-mediated transfection, lipofection, or electroporation.

[0171]   A host cell of the invention can be used to produce (i.e., express) a 22437 protein. Accordingly, the invention further provides methods for producing a 22437 protein using the

host cells of the invention. In one embodiment, the method includes culturing the host cell of the invention (into which a recombinant expression vector encoding a 22437 protein has been introduced) in a suitable medium such that a 22437 protein is produced. In another embodiment, the method further includes isolating a 22437 protein from the medium or the host

5   cell.

[0172]   In another aspect, the invention features, a cell or purified preparation of cells which include a 22437 transgene, or which otherwise mal-express 22437. The cell preparation can consist of human or non-human cells, e.g., rodent cells, e.g., mouse or rat cells, rabbit cells, or pig cells. In preferred embodiments, the cell or cells include a 22437 transgene, e.g., a

10   heterologous form of a 22437, e.g., a gene derived from humans (in the case of a non-human cell). The 22437 transgene can be mal-expressed, e.g., over-expressed or under-expressed. In other preferred embodiments, the cell or cells include a gene that mal-expresses an endogenous 22437, e.g., a gene the expression of which is disrupted, e.g., a knockout. Such cells can serve as a model for studying disorders that are related to mutated or mal-expressed 22437 alleles or

15   for use in drug screening.

[0173]   In another aspect, the invention includes, a human cell, e.g., a hematopoietic stem cell, transformed with nucleic acid that encodes a subject 22437 polypeptide.

[0174]   Also provided are cells, preferably human cells, e.g., human hematopoietic or fibroblast cells, in which an endogenous 22437 is under the control of a regulatory sequence

20   that does not normally control expression of the endogenous 22437 gene. The expression characteristics of an endogenous gene within a cell, e.g., a cell line or microorganism, can be modified by inserting a heterologous DNA regulatory element into the genome of the cell such that the inserted regulatory element is operably linked to the endogenous 22437 gene. For example, an endogenous 22437 gene that is "transcriptionally silent," e.g., not normally

25   expressed, or expressed only at very low levels, can be activated by inserting a regulatory element that is capable of promoting the expression of a normally expressed gene product in that cell. Techniques such as targeted homologous recombination, can be used to insert the heterologous DNA as described (e.g., U.S. Patent number 5,272,071; PCT publication number WO 91/06667).

30

-42-

[0175] Transgenic Animals

[0176] The invention provides non-human transgenic animals. Such animals are useful for studying the function and/or activity of a 22437 protein and for identifying and/or evaluating modulators of 22437 activity. As used herein, a "transgenic animal" is a non-human animal,

5   preferably a mammal, more preferably a rodent such as a rat or mouse, in which one or more of the cells of the animal includes a transgene. Other examples of transgenic animals include non-human primates, sheep, dogs, cows, goats, chickens, amphibians, and the like. A transgene is exogenous DNA or a rearrangement, e.g., a deletion of endogenous chromosomal DNA, which preferably is integrated into or occurs in the genome of the cells of a transgenic animal. A

10 transgene can direct the expression of an encoded gene product in one or more cell types or tissues of the transgenic animal, other transgenes, e.g., a knockout, reduce expression. Thus, a transgenic animal can be one in which an endogenous 22437 gene has been altered, e.g., by homologous recombination between the endogenous gene and an exogenous DNA molecule introduced into a cell of the animal (e.g., an embryonic cell of the animal, prior to development

15 of the animal).

[0177] Intronic sequences and polyadenylation signals can also be included in the transgene to increase the efficiency of expression of the transgene. A tissue-specific regulatory sequence(s) can be operably linked to a transgene of the invention to direct expression of a 22437 protein to particular cells. A transgenic founder animal can be identified based upon the

20 presence of a 22437 transgene in its genome and/or expression of 22437 mRNA in tissues or cells of the animals. A transgenic founder animal can then be used to breed additional animals carrying the transgene. Moreover, transgenic animals carrying a transgene encoding a 22437 protein can further be bred to other transgenic animals carrying other transgenes.

[0178] 22437 proteins or polypeptides can be expressed in transgenic animals or plants,

25 e.g., a nucleic acid encoding the protein or polypeptide can be introduced into the genome of an animal. In preferred embodiments the nucleic acid is placed under the control of a tissue specific promoter, e.g., a milk- or egg-specific promoter, and recovered from the milk or eggs produced by the animal. Suitable animals are mice, pigs, cows, goats, and sheep.

[0179] The invention also includes a population of cells from a transgenic animal, as

30 discussed, e.g., below.

- 43 -

[0180] Uses

[0181] The nucleic acid molecules, proteins, protein homologues, and antibodies described herein can be used in one or more of the following methods: a) screening assays; b) predictive medicine (e.g., diagnostic assays, prognostic assays, monitoring clinical trials, and pharmacogenetics); and c) methods of treatment (e.g., therapeutic and prophylactic). The isolated nucleic acid molecules of the invention can be used, for example, to express a 22437 protein (e.g., via a recombinant expression vector in a host cell in gene therapy applications), to detect a 22437 mRNA (e.g., in a biological sample), to detect a genetic alteration in a 22437 gene and to modulate 22437 activity, as described further below. The 22437 proteins can be used to treat disorders characterized by insufficient or excessive production of a 22437 substrate or production of 22437 inhibitors. In addition, the 22437 proteins can be used to screen for naturally occurring 22437 substrates, to screen for drugs or compounds which modulate 22437 activity, as well as to treat disorders characterized by insufficient or excessive production of 22437 protein or production of 22437 protein forms which have decreased, aberrant or unwanted activity compared to 22437 wild-type protein. Examples of such disorders include those in which sulfatase activity is aberrant or formation or hydrolysis of sulfate ester bonds is aberrant (e.g., multiple- sulfatase deficiency, metachromatic leukodystrophy, lysosomal enzyme deficiency, arylsulfatase A pseudodeficiency, elevated steroid sulfatase expression in breast cancers, mucopolysaccharidoses types II and VI, sphingolipidoses, Sneddon syndrome, androgenic alopecia, Maroteaux-Lamy syndrome, and X-linked ichthyosis). Moreover, the anti-22437 antibodies of the invention can be used to detect and isolate 22437 proteins, regulate the bioavailability of 22437 proteins, and modulate 22437 activity.

[0182] A method of evaluating a compound for the ability to interact with, e.g., bind to, a subject 22437 polypeptide is provided. The method includes: contacting the compound with the subject 22437 polypeptide; and evaluating the ability of the compound to interact with, e.g., to bind or form a complex with, the subject 22437 polypeptide. This method can be performed in vitro, e.g., in a cell free system, or in vivo, e.g., in a two-hybrid interaction trap assay. This method can be used to identify naturally-occurring molecules that interact with a subject 22437

- 44 -

polypeptide. It can also be used to find natural or synthetic inhibitors of a subject 22437 polypeptide. Screening methods are discussed in more detail below.

[0183] Screening Assays

[0184] The invention provides screening methods (also referred to herein as "assays") for identifying modulators, i.e., candidate or test compounds or agents (e.g., proteins, peptides, peptidomimetics, peptoids, small molecules or other drugs) which bind with 22437 proteins, have a stimulatory or inhibitory effect on, for example, 22437 expression or 22437 activity, or have a stimulatory or inhibitory effect on, for example, the expression or activity of a 22437 substrate. Compounds thus identified can be used to modulate the activity of target gene products (e.g., 22437 genes) in a therapeutic protocol, to elaborate the biological function of the target gene product, or to identify compounds that disrupt normal target gene interactions.

[0185] In one embodiment, the invention provides assays for screening candidate or test compounds that are substrates of a 22437 protein or polypeptide or a biologically active portion thereof. In another embodiment, the invention provides assays for screening candidate or test compounds that bind to or modulate the activity of a 22437 protein or polypeptide or a biologically active portion thereof.

[0186] In another embodiment, the invention provides assays for screening candidate or test compounds that mimic a substrate of a 22437 protein or which otherwise interfere with the normal interaction between 22437 protein and its physiological substrate. 22437 protein can interact with and degrade extracellular matrix components, thereby facilitating movement of cells into or through the matrix. Candidate or test compounds which mimic or duplicate part of the chemical structure of extracellular matrix can therefore be screened to assess their effect on the sulfatase or matrix-degrading activity of 22437 protein. Preferably, such candidate or test compounds mimic or duplicate a portion of a matrix component that normally comprises a sulfate bond, except that in the candidate or test compound the sulfate moiety has been replaced by another (e.g., phosphate, carbonyl, or metal) moiety. These screening methods can be used to assess the effectiveness of a candidate or test compound for modulating movement of cells into or through extracellular matrix. Thus, these methods are suitable both for assessing the ability of a test or candidate compound to enhance the ability of neurons to extend to or toward

- 45 -

other neurons and form new synapses therewith and for assessing the ability of a test or candidate compound to inhibit growth or metastasis of tumor cells.

[0187]   The test compounds of the present invention can be obtained using any of the numerous approaches in combinatorial library methods known in the art, including: biological libraries; peptoid libraries (libraries of molecules having the functionalities of peptides, but with a novel, non-peptide backbone which are resistant to enzymatic degradation but which nevertheless remain bioactive; e.g., Zuckermann et al., 1994, J. Med. Chem. 37:2678-2685); spatially addressable parallel solid phase or solution phase libraries; synthetic library methods requiring deconvolution; the 'one-bead one-compound' library method; and synthetic library methods using affinity chromatography selection. The biological library and peptoid library approaches are limited to peptide libraries, while the other four approaches are applicable to peptide, non-peptide oligomer or small molecule libraries of compounds (Lam, 1997, Anticancer Drug Des. 12:145).

[0188]   Examples of methods for the synthesis of molecular libraries have been described (e.g., DeWitt et al., 1993, Proc. Natl. Acad. Sci. USA 90:6909; Erb et al., 1994, Proc. Natl. Acad. Sci. USA 91:11422; Zuckermann et al., 1994, J. Med. Chem. 37:2678; Cho et al., 1993, Science 261:1303; Carrell et al., 1994, Angew. Chem. Int. Ed. Engl. 33:2059; Carell et al., 1994, Angew. Chem. Int. Ed. Engl. 33:2061; and Gallop et al., 1994, J. Med. Chem. 37:1233).

[0189]   Libraries of compounds can be presented in solution (e.g., Houghten, 1992, Biotechniques 13:412-421), or on beads (Lam, 1991, Nature 354:82-84), chips (Fodor, 1993, Nature 364:555-556), bacteria (U.S. Patent number 5,223,409), spores (U.S. Patent number 5,223,409), plasmids (Cull et al., 1992, Proc. Natl. Acad. Sci. USA 89:1865-1869), or on phage (Scott et al., 1990, Science 249:386-390; Devlin, 1990, Science 249:404-406; Cwirla et al., 1990, Proc. Natl. Acad. Sci. USA 87:6378-6382; Felici, 1991, J. Mol. Biol. 222:301-310; U.S. Patent number 5,223,409).

[0190]   In one embodiment, an assay is a cell-based assay in which a cell which expresses a 22437 protein or biologically active portion thereof is contacted with a test compound, and the ability of the test compound to modulate 22437 activity is determined. Determining the ability of the test compound to modulate 22437 activity can be accomplished by monitoring, for

example, changes in enzymatic activity. The cell, for example, can be of mammalian origin.

[0191] The ability of the test compound to modulate 22437 binding to a compound, e.g., a 22437 substrate, or to bind to 22437 can also be evaluated. This can be accomplished, for example, by coupling the compound, e.g., the substrate, with a radioisotope or enzymatic label such that binding of the compound, e.g., the substrate, to 22437 can be determined by detecting the labeled compound, e.g., substrate, in a complex. Alternatively, 22437 could be coupled with a radioisotope or enzymatic label to monitor the ability of a test compound to modulate 22437 binding to a 22437 substrate in a complex. For example, compounds (e.g., 22437 substrates) can be labeled with ^{125}I, ^{35}S, ^{14}C, or ^{3}H, either directly or indirectly, and the radioisotope detected by direct counting of radio-emission or by scintillation counting. Alternatively, compounds can be enzymatically labeled with, for example, horseradish peroxidase, alkaline phosphatase, or luciferase, and the enzymatic label detected by determination of conversion of an appropriate substrate to product.

[0192] The ability of a compound (e.g., a 22437 substrate) to interact with 22437 with or without the labeling of any of the interactants can be evaluated. For example, a microphysiometer can be used to detect the interaction of a compound with 22437 without the labeling of either the compound or the 22437 (McConnell et al., 1992, Science 257:1906-1912). As used herein, a "microphysiometer" (e.g., Cytosensor) is an analytical instrument that measures the rate at which a cell acidifies its environment using a light-addressable potentiometric sensor (LAPS). Changes in this acidification rate can be used as an indicator of the interaction between a compound and 22437.

[0193] In yet another embodiment, a cell-free assay is provided in which a 22437 protein or biologically active portion thereof is contacted with a test compound and the ability of the test compound to bind to the 22437 protein or biologically active portion thereof is evaluated. Preferred biologically active portions of the 22437 proteins to be used in assays of the present invention include fragments that participate in interactions with non-22437 molecules, e.g., fragments with high surface probability scores.

[0194] Soluble and/or membrane-bound forms of isolated proteins (e.g., 22437 proteins or biologically active portions thereof) can be used in the cell-free assays of the invention. When

membrane-bound forms of the protein are used, it can be desirable to utilize a solubilizing agent. Examples of such solubilizing agents include non-ionic detergents such as n-octylglucoside, n-dodecylglucoside, n-dodecylmaltoside, octanoyl-N-methylglucamide, decanoyl-N-methylglucamide, Triton® X-100, Triton® X-114, Thesit®,

5   Isotridecypoly(ethylene glycol ether)n, 3-{(3-cholamidopropyl) dimethylammino}-1-propane sulfonate (CHAPS), 3-{(3-cholamidopropyl) dimethylammino}-2-hydroxy-1-propane sulfonate (CHAPSO), or N-dodecyl-N,N-dimethyl-3-ammonio-1-propane sulfonate.

[0195]   Cell-free assays involve preparing a reaction mixture of the target gene protein and the test compound under conditions and for a time sufficient to allow the two components to
10   interact and bind, thus forming a complex that can be removed and/or detected.

[0196]   The interaction between two molecules can also be detected, e.g., using fluorescence energy transfer (FET; e.g., U.S. Patent number 5,631,169; U.S. Patent number 4,868,103). A fluorophore label is selected such that a first donor molecule's emitted fluorescent energy will be absorbed by a fluorescent label on a second, 'acceptor' molecule, which in turn is able to
15   fluoresce due to the absorbed energy. Alternately, the 'donor' protein molecule can simply utilize the natural fluorescent energy of tryptophan residues. Labels are chosen that emit different wavelengths of light, such that the 'acceptor' molecule label can be differentiated from that of the 'donor.' Since the efficiency of energy transfer between the labels is related to the distance separating the molecules, the spatial relationship between the molecules can be
20   assessed. In a situation in which binding occurs between the molecules, the fluorescent emission of the 'acceptor' molecule label in the assay should be maximal. An FET binding event can be conveniently measured through standard fluorometric detection means well known in the art (e.g., using a fluorimeter).

[0197]   In another embodiment, determining the ability of the 22437 protein to bind to a
25   target molecule can be accomplished using real-time biomolecular interaction analysis (BIA; e.g., Sjolander et al., 1991, Anal. Chem. 63:2338-2345; Szabo et al., 1995, Curr. Opin. Struct. Biol. 5:699-705). "Surface plasmon resonance" (SPR) or "BIA" detects biospecific interactions in real time, without labeling any of the interactants (e.g., BIAcore). Changes in the mass at the binding surface (indicative of a binding event) result in alterations of the refractive index of

light near the surface (the optical phenomenon of SPR), resulting in a detectable signal that can be used as an indication of real-time reactions between biological molecules.

[0198]   In one embodiment, the target gene product or the test substance is anchored onto a solid phase. The target gene product/test compound complexes anchored on the solid phase can be detected at the end of the reaction. Preferably, the target gene product can be anchored onto a solid surface, and the test compound, (which is not anchored), can be labeled, either directly or indirectly, with detectable labels discussed herein.

[0199]   It can be desirable to immobilize either 22437, an anti-22437 antibody or its target molecule to facilitate separation of complexed from non-complexed forms of one or both of the proteins, as well as to accommodate automation of the assay. Binding of a test compound to a 22437 protein, or interaction of a 22437 protein with a target molecule in the presence and absence of a candidate compound, can be accomplished in any vessel suitable for containing the reactants. Examples of such vessels include microtiter plates, test tubes, and micro-centrifuge tubes. In one embodiment, a fusion protein can be provided which adds a domain that allows one or both of the proteins to be bound to a matrix. For example, glutathione-S-transferase/22437 fusion proteins or glutathione-S-transferase/target fusion proteins can be adsorbed onto glutathione Sepharose™ beads (Sigma Chemical, St. Louis, MO) or glutathione-derivatized microtiter plates, which are then combined with the test compound or the test compound and either the non-adsorbed target protein or 22437 protein, and the mixture incubated under conditions conducive for complex formation (e.g., at physiological conditions for salt and pH). Following incubation, the beads or microtiter plate wells are washed to remove any unbound components, the matrix immobilized in the case of beads, complex determined either directly or indirectly, for example, as described above. Alternatively, the complexes can be dissociated from the matrix, and the level of 22437 binding or activity determined using standard techniques.

[0200]   Other techniques for immobilizing either a 22437 protein or a target molecule on matrices include using conjugation of biotin and streptavidin. Biotinylated 22437 protein or target molecules can be prepared from biotin- N-hydroxy-succinimide using techniques known in the art (e.g., biotinylation kit, Pierce Chemicals, Rockford, IL), and immobilized in the wells of streptavidin-coated 96 well plates (Pierce Chemical).

- 49 -

[0201] In order to conduct the assay, the non-immobilized component is added to the coated surface containing the anchored component. After the reaction is complete, non-reacted components are removed (e.g., by washing) under conditions such that any complexes formed will remain immobilized on the solid surface. The detection of complexes anchored on the solid surface can be accomplished in a number of ways. Where the previously non-immobilized component is pre-labeled, the detection of label immobilized on the surface indicates that complexes were formed. Where the previously non-immobilized component is not pre-labeled, an indirect label can be used to detect complexes anchored on the surface; e.g., using a labeled antibody specific for the immobilized component (the antibody, in turn, can be directly labeled or indirectly labeled with, e.g., a labeled anti-Ig antibody).

[0202] In one embodiment, this assay is performed utilizing antibodies reactive with 22437 protein or target molecules but which do not interfere with binding of the 22437 protein to its target molecule. Such antibodies can be derivatized to the wells of the plate, and unbound target or 22437 protein trapped in the wells by antibody conjugation. Methods for detecting such complexes, in addition to those described above for the GST-immobilized complexes, include immunodetection of complexes using antibodies reactive with the 22437 protein or target molecule, as well as enzyme-linked assays which rely on detecting an enzymatic activity associated with the 22437 protein or target molecule.

[0203] Alternatively, cell free assays can be conducted in a liquid phase. In such an assay, the reaction products are separated from non-reacted components, by any of a number of standard techniques, including, but not limited to: differential centrifugation (e.g., Rivas et al., 1993, Trends Biochem. Sci. 18:284-287); chromatography (e.g., gel filtration chromatography or ion-exchange chromatography); electrophoresis (e.g., Ausubel et al., eds., 1999, Current Protocols in Molecular Biology, J. Wiley, New York); and immunoprecipitation (e.g., Ausubel, supra). Such resins and chromatographic techniques are known to one skilled in the art (e.g., Heegaard, 1998, J. Mol. Recognit. 11:141-148; Hage et al., 1997, J. Chromatogr. B Biomed. Sci. Appl. 699:499-525). Further, fluorescence energy transfer can also be conveniently utilized, as described herein, to detect binding without further purification of the complex from solution.

[0204] In a preferred embodiment, the assay includes contacting the 22437 protein or biologically active portion thereof with a known compound which binds 22437 to form an assay mixture, contacting the assay mixture with a test compound, and determining the ability of the test compound to interact with a 22437 protein, wherein determining the ability of the test compound to interact with a 22437 protein includes determining the ability of the test compound to preferentially bind to 22437 or biologically active portion thereof, or to modulate the activity of a target molecule, as compared to the known compound.

[0205] The target gene products of the invention can, in vivo, interact with one or more cellular or extracellular macromolecules, such as proteins. For the purposes of this discussion, such cellular and extracellular macromolecules are referred to herein as "binding partners." Compounds that disrupt such interactions can be useful in regulating the activity of the target gene product. Such compounds can include, but are not limited to molecules such as antibodies, peptides, and small molecules. The preferred target genes/products for use in this embodiment are the 22437 genes herein identified. In an alternative embodiment, the invention provides methods for determining the ability of the test compound to modulate the activity of a 22437 protein through modulation of the activity of a downstream effector of a 22437 target molecule. For example, the activity of the effector molecule on an appropriate target can be determined, or the binding of the effector to an appropriate target can be determined, as previously described.

[0206] To identify compounds that interfere with the interaction between the target gene product and its cellular or extracellular binding partner(s), a reaction mixture containing the target gene product and the binding partner is prepared, under conditions and for a time sufficient, to allow the two products to form complex. In order to test an inhibitory agent, the reaction mixture is provided in the presence and absence of the test compound. The test compound can be initially included in the reaction mixture, or can be added at a time subsequent to the addition of the target gene and its cellular or extracellular binding partner. Control reaction mixtures are incubated without the test compound or with a placebo. The formation of any complexes between the target gene product and the cellular or extracellular binding partner is then detected. The formation of a complex in the control reaction, but not in the reaction mixture containing the test compound, indicates that the compound interferes with

the interaction of the target gene product and the interactive binding partner. Additionally, complex formation within reaction mixtures containing the test compound and normal target gene product can also be compared to complex formation within reaction mixtures containing the test compound and mutant target gene product. This comparison can be important in those cases wherein it is desirable to identify compounds that disrupt interactions of mutant but not normal target gene products.

[0207]   These assays can be conducted in a heterogeneous or homogeneous format. Heterogeneous assays involve anchoring either the target gene product or the binding partner onto a solid phase, and detecting complexes anchored on the solid phase at the end of the reaction. In homogeneous assays, the entire reaction is carried out in a liquid phase. In either approach, the order of addition of reactants can be varied to obtain different information about the compounds being tested. For example, test compounds that interfere with the interaction between the target gene products and the binding partners, e.g., by competition, can be identified by conducting the reaction in the presence of the test substance. Alternatively, test compounds that disrupt preformed complexes, e.g., compounds with higher binding constants that displace one of the components from the complex, can be tested by adding the test compound to the reaction mixture after complexes have been formed. The various formats are briefly described below.

[0208]   In a heterogeneous assay system, either the target gene product or the interactive cellular or extracellular binding partner, is anchored onto a solid surface (e.g., a microtiter plate), while the non-anchored species is labeled, either directly or indirectly. The anchored species can be immobilized by non-covalent or covalent attachments. Alternatively, an immobilized antibody specific for the species to be anchored can be used to anchor the species to the solid surface.

[0209]   In order to conduct the assay, the partner of the immobilized species is exposed to the coated surface with or without the test compound. After the reaction is complete, non-reacted components are removed (e.g., by washing) and any complexes formed will remain immobilized on the solid surface. Where the non-immobilized species is pre-labeled, the detection of label immobilized on the surface indicates that complexes were formed. Where the non-immobilized species is not pre-labeled, an indirect label can be used to detect complexes

- 52 -

anchored on the surface; e.g., using a labeled antibody specific for the initially non-immobilized species (the antibody, in turn, can be directly labeled or indirectly labeled with, e.g., a labeled anti-Ig antibody). Depending upon the order of addition of reaction components, test compounds that inhibit complex formation or that disrupt preformed complexes can be detected.

[0210] Alternatively, the reaction can be conducted in a liquid phase in the presence or absence of the test compound, the reaction products separated from non-reacted components, and complexes detected; e.g., using an immobilized antibody specific for one of the binding components to anchor any complexes formed in solution, and a labeled antibody specific for the other partner to detect anchored complexes. Again, depending upon the order of addition of reactants to the liquid phase, test compounds that inhibit complex or that disrupt preformed complexes can be identified.

[0211] In an alternate embodiment of the invention, a homogeneous assay can be used. For example, a pre-formed complex of the target gene product and the interactive cellular or extracellular binding partner product is prepared in that either the target gene products or their binding partners are labeled, but the signal generated by the label is quenched due to complex formation (e.g., U.S. Patent number 4,109,496 that utilizes this approach for immunoassays). The addition of a test substance that competes with and displaces one of the species from the preformed complex will result in the generation of a signal above background. In this way, test substances that disrupt target gene product-binding partner interaction can be identified.

[0212] In yet another aspect, the 22437 proteins can be used as "bait proteins" in a two-hybrid assay or three-hybrid assay (e.g., U.S. Patent number 5,283,317; Zervos et al., 1993, Cell 72:223-232; Madura et al., 1993, J. Biol. Chem. 268:12046-12054; Bartel et al., 1993, Biotechniques 14:920-924; Iwabuchi et al., 1993, Oncogene 8:1693-1696; PCT publication number WO 94/10300), to identify other proteins, which bind to or interact with 22437 ("22437-binding proteins" or "22437-bp") and are involved in 22437 activity. Such 22437-bps can be activators or inhibitors of signals by the 22437 proteins or 22437 targets as, for example, downstream elements of a 22437-mediated signaling pathway.

[0213] The two-hybrid system is based on the modular nature of most transcription factors, which consist of separable DNA-binding and activation domains. Briefly, the assay utilizes

- 53 -

two different DNA constructs. In one construct, the gene that codes for a 22437 protein is fused to a gene encoding the DNA binding domain of a known transcription factor (e.g., GAL-4). In the other construct, a DNA sequence, from a library of DNA sequences, that encodes an unidentified protein ("prey" or "sample") is fused to a gene that codes for the activation domain

5   of the known transcription factor. (Alternatively, the 22437 protein can be fused to the activator domain). If the "bait" and the "prey" proteins are able to interact in vivo forming a 22437-dependent complex, the DNA-binding and activation domains of the transcription factor are brought into close proximity. This proximity allows transcription of a reporter gene (e.g., LacZ) that is operably linked to a transcriptional regulatory site responsive to the transcription

10   factor. Expression of the reporter gene can be detected and cell colonies containing the functional transcription factor can be isolated and used to obtain the cloned gene that encodes the protein that interacts with the 22437 protein.

[0214]   In another embodiment, modulators of 22437 expression are identified. For example, a cell or cell free mixture is contacted with a candidate compound and the expression

15   of 22437 mRNA or protein evaluated relative to the level of expression of 22437 mRNA or protein in the absence of the candidate compound. When expression of 22437 mRNA or protein is greater in the presence of the candidate compound than in its absence, the candidate compound is identified as a stimulator of 22437 mRNA or protein expression. Alternatively, when expression of 22437 mRNA or protein is less (i.e., statistically significantly less) in the

20   presence of the candidate compound than in its absence, the candidate compound is identified as an inhibitor of 22437 mRNA or protein expression. The level of 22437 mRNA or protein expression can be determined by methods described herein for detecting 22437 mRNA or protein.

[0215]   In another aspect, the invention pertains to a combination of two or more of the

25   assays described herein. For example, a modulating agent can be identified using a cell-based or a cell free assay, and the ability of the agent to modulate the activity of a 22437 protein can be confirmed in vivo, e.g., in an animal such as an animal model for a disease.

[0216]   This invention further pertains to novel agents identified by the above-described screening assays. Accordingly, it is within the scope of this invention to further use an agent

30   identified as described herein (e.g., a 22437 modulating agent, an antisense 22437 nucleic acid

molecule, a 22437-specific antibody, or a 22437-binding partner) in an appropriate animal model to determine the efficacy, toxicity, side effects, or mechanism of action, of treatment with such an agent. Furthermore, novel agents identified by the above-described screening assays can be used for treatments as described herein.

5

[0217]   Detection Assays

[0218]   Portions or fragments of the nucleic acid sequences identified herein can be used as polynucleotide reagents. For example, these sequences can be used to: (i) map their respective genes on a chromosome, e.g., to locate gene regions associated with genetic disease or to

10   associate 22437 with a disease; (ii) identify an individual from a minute biological sample (tissue typing); and (iii) aid in forensic identification of a biological sample. These applications are described in the subsections below.

[0219]   Chromosome Mapping

15   [0220]   The 22437 nucleotide sequences or portions thereof can be used to map the location of the 22437 genes on a chromosome. This process is called chromosome mapping. Chromosome mapping is useful in correlating the 22437 sequences with genes associated with disease.

[0221]   Briefly, 22437 genes can be mapped to chromosomes by preparing PCR primers

20   (preferably 15-25 base pairs in length) from the 22437 nucleotide sequence (e.g., SEQ ID NO: 1 or SEQ ID NO: 3). These primers can then be used for PCR screening of somatic cell hybrids containing individual human chromosomes. Only those hybrids containing the human gene corresponding to the 22437 sequences will yield an amplified fragment.

[0222]   A panel of somatic cell hybrids in which each cell line contains either a single

25   human chromosome or a small number of human chromosomes, and a full set of mouse chromosomes, can allow easy mapping of individual genes to specific human chromosomes (D'Eustachio et al., 1983, Science 220:919-924).

[0223]   Other mapping strategies e.g., in situ hybridization as described (Fan et al., 1990, Proc. Natl. Acad. Sci. USA 87:6223-6227), pre-screening with labeled flow-sorted

- 55 -

chromosomes, and pre-selection by hybridization to chromosome specific cDNA libraries can be used to map 22437 to a chromosomal location.

[0224] Fluorescence in situ hybridization (FISH) of a DNA sequence to a metaphase chromosomal spread can further be used to provide a precise chromosomal location in one step. The FISH technique can be used with a DNA sequence as short as 500 or 600 bases. However, clones larger than 1,000 bases have a higher likelihood of binding to a unique chromosomal location with sufficient signal intensity for simple detection. Preferably 1,000 bases, and more preferably 2,000 bases will suffice to get good results at a reasonable amount of time. For a review of FISH, see Verma et al. (1988, Human Chromosomes: A Manual of Basic Techniques, Pergamon Press, New York).

[0225] Reagents for chromosome mapping can be used individually to mark a single chromosome or a single site on that chromosome, or panels of reagents can be used for marking multiple sites and/or multiple chromosomes. Reagents corresponding to non-coding regions of the genes are typically preferred for mapping purposes. Coding sequences are more likely to be conserved within gene families, thus increasing the chance of cross hybridizations during chromosomal mapping.

[0226] Once a sequence has been mapped to a precise chromosomal location, the physical position of the sequence on the chromosome can be correlated with genetic map data (such data are found, for example, in V. McKusick, Mendelian Inheritance in Man, available on-line through Johns Hopkins University Welch Medical Library). The relationship between a gene and a disease, mapped to the same chromosomal region, can then be identified through linkage analysis (co-inheritance of physically adjacent genes), as described (e.g., Egeland et al., 1987, Nature, 325:783-787).

[0227] Moreover, differences in the DNA sequences between individuals affected and unaffected with a disease associated with the 22437 gene, can be determined. If a mutation is observed in some or all of the affected individuals but not in any unaffected individuals, then the mutation is likely to be the causative agent of the particular disease. Comparison of affected and unaffected individuals generally involves first looking for structural alterations in the chromosomes, such as deletions or translocations that are visible from chromosome spreads or detectable using PCR based on that DNA sequence. Ultimately, complete sequencing of

- 56 -

genes from several individuals can be performed to confirm the presence of a mutation and to distinguish mutations from polymorphisms.

[0228] Tissue Typing

[0229] 22437 sequences can be used to identify individuals from biological samples using, e.g., restriction fragment length polymorphism (RFLP). In this technique, an individual's genomic DNA is digested with one or more restriction enzymes, the fragments separated, e.g., in a Southern blot, and probed to yield bands for identification. The sequences of the present invention are useful as additional DNA markers for RFLP (described in U.S. Patent number 5,272,057).

[0230] Furthermore, the sequences of the present invention can also be used to determine the actual base-by-base DNA sequence of selected portions of an individual's genome. Thus, the 22437 nucleotide sequence described herein can be used to prepare PCR primers homologous to the 5'- and 3'-ends of the sequence. These primers can then be used to amplify an individual's DNA and subsequently sequence it. Panels of corresponding DNA sequences from individuals, prepared in this manner, can provide unique individual identifications, as each individual will have a unique set of such DNA sequences due to allelic differences.

[0231] Allelic variation occurs to some degree in the coding regions of these sequences, and to a greater degree in the non-coding regions. Each of the sequences described herein can, to some degree, be used as a standard against which DNA from an individual can be compared for identification purposes. Because greater numbers of polymorphisms occur in the non-coding regions, fewer sequences are necessary to differentiate individuals. The non-coding sequences of SEQ ID NO: 1 can provide positive individual identification with a panel of perhaps 10 to 1,000 primers which each yield a non-coding amplified sequence of 100 bases. If predicted coding sequences are used, such as those in SEQ ID NO: 3, a more appropriate number of primers for positive individual identification would be 500-2,000.

[0232] If a panel of reagents from 22437 nucleotide sequences described herein is used to generate a unique identification database for an individual, those same reagents can later be used to identify tissue from that individual. Using the unique identification database, positive

identification of the individual, living or dead, can be made from extremely small tissue samples.

[0233]   Use of Partial 22437 Sequences in Forensic Biology

[0234]   DNA-based identification techniques can also be used in forensic biology. To make such an identification, PCR technology can be used to amplify DNA sequences taken from very small biological samples such as tissues, e.g., hair or skin, or body fluids, e.g., blood, saliva, or semen found at a crime scene. The amplified sequence can then be compared to a standard, thereby allowing identification of the origin of the biological sample.

[0235]   The sequences of the present invention can be used to provide polynucleotide reagents, e.g., PCR primers, targeted to specific loci in the human genome, which can enhance the reliability of DNA-based forensic identifications by, for example, providing another "identification marker" (i.e., another DNA sequence that is unique to a particular individual). As mentioned above, actual nucleotide sequence information can be used for identification as an accurate alternative to patterns formed by restriction enzyme generated fragments. Sequences targeted to non-coding regions of SEQ ID NO: 1 (e.g., fragments having a length of at least 20 nucleotide residues, preferably at least 30 nucleotide residues) are particularly appropriate for this use.

[0236]   The 22437 nucleotide sequences described herein can further be used to provide polynucleotide reagents, e.g., labeled or label-able probes which can be used in, for example, an in situ hybridization technique, to identify a specific tissue, e.g., a tissue containing hematopoietic cells. This can be very useful in cases where a forensic pathologist is presented with a tissue of unknown origin. Panels of such 22437 probes can be used to identify tissue by species and/or by organ type.

[0237]   In a similar fashion, these reagents, e.g., 22437 primers or probes can be used to screen tissue culture for contamination (i.e., to screen for the presence of a mixture of different types of cells in a culture).

- 58 -

[0238] Predictive Medicine

[0239] The present invention also pertains to the field of predictive medicine in which diagnostic assays, prognostic assays, and monitoring clinical trials are used for prognostic (predictive) purposes to thereby treat an individual.

[0240] Generally, the invention provides a method of determining if a subject is at risk for a disorder related to a lesion in, or the malexpression of, a gene that encodes a 22437 polypeptide.

[0241] Such disorders include, e.g., a disorder associated with the malexpression of a 22437 polypeptide, such as a disorder relating to sulfate metabolism aberrant formation or hydrolysis of sulfate ester bonds (e.g., multiple-sulfatase deficiency, metachromatic leukodystrophy, lysosomal enzyme deficiency, arylsulfatase A pseudodeficiency, elevated steroid sulfatase expression in breast cancers, mucopolysaccharidoses types II and VI, sphingolipidoses, Sneddon syndrome, androgenic alopecia, Maroteaux-Lamy syndrome, and X-linked ichthyosis).

[0242] As the data disclosed herein demonstrate, expression of the 22437 gene is associated with growth and metastasis of tumor cells, particularly with growth and metastasis of epithelial tumor cells (e.g., cells of ovarian, colon, breast, and lung tumors). Thus, detection (organism-wide or in a particular tissue or cell sample) of mutations which affect expression of the 22437 gene can indicate whether an individual exhibits a greater or lesser propensity to develop a tumor and whether such a tumor is likely to grow and metastasize. Such detection can be used, for example, to weigh the risks and benefits of a cancer prevention method for an individual or to inform the opinion of a medical practitioner regarding the aggressiveness with which an existing tumor in an individual should be treated.

[0243] Expression of the 22437 gene is also associated with the ability of vascular endothelial cells to move into or through extracellular matrix, thereby facilitating generation of new blood vessels and extension of existing vessels (i.e., angiogenesis). Aberrant angiogenesis is associated with numerous disorders, including tumor formation and growth and various retinopathies. Wound healing also requires that sufficient angiogenesis occur to provide the healed tissue with adequate blood supply. Thus, detection of mutations which affect expression of the 22437 gene can indicate whether an individual exhibits a greater or lesser propensity for

- 59 -

tumor establishment and growth or whether an individual will likely require pharmaceutical intervention in order to optimize wound healing.

[0244] In addition, expression of the 22437 gene is associated with the ability of certain nerve tissues (e.g., astrocytes and other neurons of the cerebral cortex) to move or extend through or into extracellular matrix in order to establish or re-establish connections with other neurons. Detection of mutations which affect expression of the 22437 gene can, for example, indicate the propensity of an individual's neurons to re-connect with one another following traumatic neuronal injury (e.g., cerebral ischemic damage associated with a stroke).

[0245] The method includes one or more of the following:

(i) detecting, in a tissue of the subject, the presence or absence of a mutation which affects the expression of the 22437 gene, or detecting the presence or absence of a mutation in a region which controls the expression of the gene, e.g., a mutation in the 5'-control region;

(ii) detecting, in a tissue of the subject, the presence or absence of a mutation which alters the structure of the 22437 gene;

(iii) detecting, in a tissue of the subject, the malexpression of the 22437 gene at the mRNA level, e.g., detecting a non-wild-type level of a mRNA; and

(iv) detecting, in a tissue of the subject, the malexpression of the gene at the protein level, e.g., detecting a non-wild-type level of a 22437 polypeptide.

[0246] In preferred embodiments the method includes: ascertaining the existence of at least one of: a deletion of one or more nucleotides from the 22437 gene; an insertion of one or more nucleotides into the gene, a point mutation, e.g., a substitution of one or more nucleotides of the gene, a gross chromosomal rearrangement of the gene, e.g., a translocation, inversion, or deletion.

[0247] For example, detecting the genetic lesion can include: (i) providing a probe/primer including an oligonucleotide containing a region of nucleotide sequence which hybridizes to a sense or antisense sequence from SEQ ID NO: 1, or naturally occurring mutants thereof, or 5'- or 3'-flanking sequences naturally associated with the 22437 gene; (ii) exposing the probe/primer to nucleic acid of the tissue; and detecting the presence or absence of the genetic lesion by hybridization of the probe/primer to the nucleic acid, e.g., by in situ hybridization.

- 60 -

[0248]   In preferred embodiments, detecting the malexpression includes ascertaining the existence of at least one of: an alteration in the level of a messenger RNA transcript of the 22437 gene; the presence of a non-wild-type splicing pattern of a messenger RNA transcript of the gene; or a non-wild-type level of 22437 RNA or protein.

[0249]   Methods of the invention can be used for prenatal screening or to determine if a subject's offspring will be at risk for a disorder.

[0250]   In preferred embodiments the method includes determining the structure of a 22437 gene, an abnormal structure being indicative of risk for the disorder.

[0251]   In preferred embodiments the method includes contacting a sample form the subject with an antibody to the 22437 protein or a nucleic acid, which hybridizes specifically with the gene. These and other embodiments are discussed below.

[0252]   Diagnostic and Prognostic Assays

[0253]   The presence, level, or absence of 22437 protein or nucleic acid in a biological sample can be evaluated by obtaining a biological sample from a test subject and contacting the biological sample with a compound or an agent capable of detecting 22437 protein or nucleic acid (e.g., mRNA, genomic DNA) that encodes 22437 protein such that the presence of 22437 protein or nucleic acid is detected in the biological sample. The term "biological sample" includes tissues, cells and biological fluids isolated from a subject, as well as tissues, cells and fluids present within a subject. A preferred biological sample is serum, a tumor biopsy sample, or ascites. The level of expression of the 22437 gene can be measured in a number of ways, including, but not limited to: measuring the mRNA encoded by the 22437 genes; measuring the amount of protein encoded by the 22437 genes; or measuring the activity of the protein encoded by the 22437 genes.

[0254]   The level of mRNA corresponding to the 22437 gene in a cell can be determined both by in situ and by in vitro formats.

[0255]   The isolated mRNA can be used in hybridization or amplification assays that include, but are not limited to, Southern or Northern analyses, polymerase chain reaction analyses and probe arrays. One preferred diagnostic method for the detection of mRNA levels involves contacting the isolated mRNA with a nucleic acid molecule (probe) that can hybridize

- 61 -

to the mRNA encoded by the gene being detected. The nucleic acid probe can be, for example, a full-length 22437 nucleic acid, such as the nucleic acid of SEQ ID NO: 1 or a portion thereof, such as an oligonucleotide of at least 7, 15, 30, 50, 100, 250 or 500 nucleotides in length and sufficient to specifically hybridize under stringent conditions to 22437 mRNA or genomic

5   DNA. Other suitable probes for use in the diagnostic assays are described herein.

[0256]   In one format, mRNA (or cDNA) is immobilized on a surface and contacted with the probes, for example by running the isolated mRNA on an agarose gel and transferring the mRNA from the gel to a membrane, such as nitrocellulose. In an alternative format, the probes are immobilized on a surface and the mRNA (or cDNA) is contacted with the probes, for

10   example, in a two-dimensional gene chip array. A skilled artisan can adapt known mRNA detection methods for use in detecting the level of mRNA encoded by the 22437 genes.

[0257]   The level of mRNA in a sample that is encoded by 22437 can be evaluated with nucleic acid amplification, e.g., by RT-PCR (U.S. Patent number 4,683,202), ligase chain reaction (Barany, 1991, Proc. Natl. Acad. Sci. USA 88:189-193), self-sustained sequence

15   replication (Guatelli et al., 1990, Proc. Natl. Acad. Sci. USA 87:1874-1878), transcriptional amplification system (Kwoh et al., 1989, Proc. Natl. Acad. Sci. USA 86:1173-1177), Q-Beta Replicase (Lizardi et al., 1988, Bio/Technology 6:1197), rolling circle replication (U.S. Patent number 5,854,033) or any other nucleic acid amplification method, followed by the detection of the amplified molecules using techniques known in the art. As used herein, amplification

20   primers are defined as being a pair of nucleic acid molecules that can anneal to 5'- or 3'-regions of a 22437 gene (plus and minus strands, respectively, or vice-versa) and contain a short region in between. In general, amplification primers are from about 10 to 30 nucleotides in length and flank a region from about 50 to 200 nucleotides in length. Under appropriate conditions and with appropriate reagents, such primers permit the amplification of a nucleic acid molecule

25   comprising the nucleotide sequence between the primers.

[0258]   For in situ methods, a cell or tissue sample can be prepared/processed and immobilized on a support, typically a glass slide, and then contacted with a probe that can hybridize to mRNA that encodes the 22437 gene being analyzed.

[0259]   In another embodiment, the methods include further contacting a control sample

30   with a compound or agent capable of detecting 22437 mRNA, or genomic DNA, and

comparing the presence of 22437 mRNA or genomic DNA in the control sample with the presence of 22437 mRNA or genomic DNA in the test sample.

[0260]   A variety of methods can be used to determine the level of protein encoded by 22437. In general, these methods include contacting an agent that selectively binds to the protein, such as an antibody with a sample, to evaluate the level of protein in the sample. In a preferred embodiment, the antibody bears a detectable label. Antibodies can be polyclonal, or more preferably, monoclonal. An intact antibody, or a fragment thereof (e.g., Fab or F(ab')$_2$) can be used. The term "labeled," with regard to the probe or antibody, is intended to encompass direct labeling of the probe or antibody by coupling (i.e., physically linking) a detectable substance to the probe or antibody, as well as indirect labeling of the probe or antibody by reactivity with a detectable substance. Examples of detectable substances are provided herein.

[0261]   The detection methods can be used to detect 22437 protein in a biological sample in vitro as well as in vivo. In vitro techniques for detection of 22437 protein include enzyme linked immunosorbent assays (ELISAs), immunoprecipitations, immunofluorescence, enzyme immunoassay (EIA), radioimmunoassay (RIA), and Western blot analysis. In vivo techniques for detection of 22437 protein include introducing into a subject a labeled anti-22437 antibody. For example, the antibody can be labeled with a radioactive marker whose presence and location in a subject can be detected by standard imaging techniques.

[0262]   In another embodiment, the methods further include contacting the control sample with a compound or agent capable of detecting 22437 protein, and comparing the presence of 22437 protein in the control sample with the presence of 22437 protein in the test sample.

[0263]   The invention also includes kits for detecting the presence of 22437 in a biological sample. For example, the kit can include a compound or agent capable of detecting 22437 protein or mRNA in a biological sample, and a standard. The compound or agent can be packaged in a suitable container. The kit can further comprise instructions for using the kit to detect 22437 protein or nucleic acid.

[0264]   For antibody-based kits, the kit can include: (1) a first antibody (e.g., attached to a solid support) which binds to a polypeptide corresponding to a marker of the invention; and,

optionally, (2) a second, different antibody which binds to either the polypeptide or the first antibody and is conjugated to a detectable agent.

[0265] For oligonucleotide-based kits, the kit can include: (1) an oligonucleotide, e.g., a detectably-labeled oligonucleotide, which hybridizes to a nucleic acid sequence encoding a polypeptide corresponding to a marker of the invention or (2) a pair of primers useful for amplifying a nucleic acid molecule corresponding to a marker of the invention. The kit can also includes a buffering agent, a preservative, or a protein-stabilizing agent. The kit can also includes components necessary for detecting the detectable agent (e.g., an enzyme or a substrate). The kit can also contain a control sample or a series of control samples that can be assayed and compared to the test sample contained. Each component of the kit can be enclosed within an individual container and all of the various containers can be within a single package, along with instructions for interpreting the results of the assays performed using the kit.

[0266] The diagnostic methods described herein can identify subjects having, or at risk of developing, a disease or disorder associated with malexpressed, aberrant or unwanted 22437 expression or activity. As used herein, the term "unwanted" includes an unwanted phenomenon involved in a biological response such as induction of an inappropriate immune response or deregulated cell proliferation.

[0267] In one embodiment, a disease or disorder associated with aberrant or unwanted 22437 expression or activity is identified. A test sample is obtained from a subject and 22437 protein or nucleic acid (e.g., mRNA or genomic DNA) is evaluated, wherein the level, e.g., the presence or absence, of 22437 protein or nucleic acid is diagnostic for a subject having or at risk of developing a disease or disorder associated with aberrant or unwanted 22437 expression or activity. As used herein, a "test sample" refers to a biological sample obtained from a subject of interest, including a biological fluid (e.g., serum), cell sample, or tissue.

[0268] The prognostic assays described herein can be used to determine whether a subject can be administered an agent (e.g., an agonist, antagonist, peptidomimetic, protein, peptide, nucleic acid, small molecule, or other drug candidate) to treat a disease or disorder associated with aberrant or unwanted 22437 expression or activity. For example, such methods can be used to determine whether a subject can be effectively treated with an agent that modulates 22437 expression or activity.

- 64 -

[0269] The methods of the invention can also be used to detect genetic alterations in a 22437 gene, thereby determining if a subject with the altered gene is at risk for a disorder characterized by misregulation in 22437 protein activity or nucleic acid expression, such as a disorder associated with aberrant sulfate metabolism or aberrant sulfatase activity. In preferred embodiments, the methods include detecting, in a sample obtained from the subject, the presence or absence of a genetic alteration characterized by at least one of an alteration affecting the integrity of a gene encoding a 22437 protein, or the malexpression of the 22437 gene. For example, such genetic alterations can be detected by ascertaining the existence of at least one of 1) a deletion of one or more nucleotides from a 22437 gene; 2) an addition of one or more nucleotides to a 22437 gene; 3) a substitution of one or more nucleotides of a 22437 gene, 4) a chromosomal rearrangement of a 22437 gene; 5) an alteration in the level of a messenger RNA transcript of a 22437 gene, 6) aberrant modification of a 22437 gene, such as of the methylation pattern of the genomic DNA, 7) the presence of a non-wild-type splicing pattern of a messenger RNA transcript of a 22437 gene, 8) a non-wild-type level of a 22437 protein, 9) allelic loss of a 22437 gene, and 10) inappropriate post-translational modification of a 22437 protein.

[0270] An alteration can be detected without a probe/primer in a polymerase chain reaction, such as anchor PCR or RACE-PCR, or, alternatively, in a ligation chain reaction (LCR), the latter of which can be particularly useful for detecting point mutations in the 22437 gene. This method can include the steps of collecting a sample of cells from a subject, isolating nucleic acid (e.g., genomic, mRNA or both) from the sample, contacting the nucleic acid sample with one or more primers which specifically hybridize to a 22437 gene under conditions such that hybridization and amplification of the 22437 gene occurs (if present), and detecting the presence or absence of an amplification product, or detecting the size of the amplification product and comparing the length to a control sample. It is anticipated that PCR and/or LCR can be desirable to use as a preliminary amplification step in conjunction with any of the techniques used for detecting mutations described herein.

[0271] Alternative amplification methods include: self sustained sequence replication (Guatelli et al., 1990, Proc. Natl. Acad. Sci. USA 87:1874-1878), transcriptional amplification system (Kwoh et al., 1989, Proc. Natl. Acad. Sci. USA 86:1173-1177), Q-Beta Replicase

(Lizardi et al., 1988, Bio/Technology 6:1197), or other nucleic acid amplification methods, followed by the detection of the amplified molecules using techniques known to those of skill in the art.

[0272] In another embodiment, mutations in a 22437 gene from a sample cell can be identified by detecting alterations in restriction enzyme cleavage patterns. For example, sample and control DNA is isolated, amplified (optionally), digested with one or more restriction endonucleases, and fragment length sizes are determined, e.g., by gel electrophoresis, and compared. Differences in fragment length sizes between sample and control DNA indicates mutations in the sample DNA. Moreover, the use of sequence specific ribozymes (e.g., U.S. Patent number 5,498,531) can be used to score for the presence of specific mutations by development or loss of a ribozyme cleavage site.

[0273] In other embodiments, genetic mutations in 22437 can be identified by hybridizing a sample to control nucleic acids, e.g., DNA or RNA, by, e.g., two-dimensional arrays, or, e.g., chip based arrays. Such arrays include a plurality of addresses, each of which is positionally distinguishable from the other. A different probe is located at each address of the plurality. The arrays can have a high density of addresses, e.g., can contain hundreds or thousands of oligonucleotides probes (Cronin et al., 1996, Hum. Mutat. 7:244-255; Kozal et al., 1996, Nature Med. 2:753-759). For example, genetic mutations in 22437 can be identified in two-dimensional arrays containing light-generated DNA probes as described (Cronin et al., supra). Briefly, a first hybridization array of probes can be used to scan through long stretches of DNA in a sample and control to identify base changes between the sequences by making linear arrays of sequential overlapping probes. This step allows the identification of point mutations. This step is followed by a second hybridization array that allows the characterization of specific mutations by using smaller, specialized probe arrays complementary to all variants or mutations detected. Each mutation array is composed of parallel probe sets, one complementary to the wild-type gene and the other complementary to the mutant gene.

[0274] In yet another embodiment, any of a variety of sequencing reactions known in the art can be used to directly sequence the 22437 gene and detect mutations by comparing the sequence of the sample 22437 with the corresponding wild-type (control) sequence. Automated

sequencing procedures can be utilized when performing the diagnostic assays (1995, Biotechniques 19:448), including sequencing by mass spectrometry.

[0275]   Other methods for detecting mutations in the 22437 gene include methods in which protection from cleavage agents is used to detect mismatched bases in RNA/RNA or RNA/DNA heteroduplexes (Myers et al., 1985, Science 230:1242; Cotton et al., 1988, Proc. Natl. Acad. Sci. USA 85:4397; Saleeba et al., 1992, Meth. Enzymol. 217:286-295).

[0276]   In still another embodiment, the mismatch cleavage reaction employs one or more proteins that recognize mismatched base pairs in double-stranded DNA (so called "DNA mismatch repair" enzymes) in defined systems for detecting and mapping point mutations in 22437 cDNAs obtained from samples of cells. For example, the mutY enzyme of E. coli cleaves A at G/A mismatches and the thymidine DNA glycosylase from HeLa cells cleaves T at G/T mismatches (Hsu et al., 1994, Carcinogenesis 15:1657-1662; U.S. Patent number 5,459,039).

[0277]   In other embodiments, alterations in electrophoretic mobility will be used to identify mutations in 22437 genes. For example, single strand conformation polymorphism (SSCP) can be used to detect differences in electrophoretic mobility between mutant and wild-type nucleic acids (Orita et al., 1989, Proc. Natl. Acad. Sci. USA 86:2766; Cotton, 1993, Mutat. Res. 285:125-144; Hayashi, 1992, Genet. Anal. Tech. Appl. 9:73-79). Single-stranded DNA fragments of sample and control 22437 nucleic acids will be denatured and allowed to re-nature. The secondary structure of single-stranded nucleic acids varies according to sequence, the resulting alteration in electrophoretic mobility enables the detection of even a single base change. The DNA fragments can be labeled or detected with labeled probes. The sensitivity of the assay can be enhanced by using RNA (rather than DNA), in which the secondary structure is more sensitive to a change in sequence. In a preferred embodiment, the subject method utilizes heteroduplex analysis to separate double stranded heteroduplex molecules on the basis of changes in electrophoretic mobility (Keen et al., 1991, Trends Genet 7:5).

[0278]   In yet another embodiment, the movement of mutant or wild-type fragments in polyacrylamide gels containing a gradient of denaturant is assayed using denaturing gradient gel electrophoresis (DGGE) (Myers et al., 1985, Nature 313:495). When DGGE is used as the method of analysis, DNA will be modified to insure that it does not completely denature, for

example by adding a GC clamp of approximately 40 base pairs of high-melting GC-rich DNA by PCR. In a further embodiment, a temperature gradient is used in place of a denaturing gradient to identify differences in the mobility of control and sample DNA (Rosenbaum and Reissner (1987) Biophys Chem 265:12753).

[0279] Examples of other techniques for detecting point mutations include, but are not limited to, selective oligonucleotide hybridization, selective amplification, or selective primer extension (Saiki et al., 1986, Nature 324:163; Saiki et al., 1989, Proc. Natl. Acad. Sci. USA 86:6230).

[0280] Alternatively, allele specific amplification technology that depends on selective PCR amplification can be used in conjunction with the instant invention. Oligonucleotides used as primers for specific amplification can carry the mutation of interest in the center of the molecule (so that amplification depends on differential hybridization; Gibbs et al., 1989, Nucl. Acids Res. 17:2437-2448) or at the extreme 3'-end of one primer where, under appropriate conditions, mismatch can prevent, or reduce polymerase extension (Prossner, 1993, Tibtech 11:238). In addition, it can be desirable to introduce a novel restriction site in the region of the mutation to create cleavage-based detection (Gasparini et al., 1992, Mol. Cell Probes 6:1). It is anticipated that in certain embodiments, amplification can also be performed using Taq ligase for amplification (Barany, 1991, Proc. Natl. Acad. Sci. USA 88:189). In such cases, ligation will occur only if there is a perfect match at the 3'-end of the 5'- sequence making it possible to detect the presence of a known mutation at a specific site by looking for the presence or absence of amplification.

[0281] The methods described herein can be performed, for example, using pre-packaged diagnostic kits comprising at least one probe nucleic acid or antibody reagent described herein, which can be conveniently used, e.g., in clinical settings to diagnose patients exhibiting symptoms or family history of a disease or illness involving a 22437 gene.

[0282] Use of 22437 Molecules as Surrogate Markers

[0283] The 22437 molecules of the invention are also useful as markers of disorders or disease states, as markers for precursors of disease states, as markers for predisposition of disease states, as markers of drug activity, or as markers of the pharmacogenomic profile of a

- 68 -

subject. Using the methods described herein, the presence, absence and/or quantity of the 22437 molecules of the invention can be detected, and can be correlated with one or more biological states in vivo. For example, the 22437 molecules of the invention can serve as surrogate markers for one or more disorders or disease states or for conditions leading up to

5   disease states. As used herein, a "surrogate marker" is an objective biochemical marker which correlates with the absence or presence of a disease or disorder, or with the progression of a disease or disorder (e.g., with the presence or absence of a tumor). The presence or quantity of such markers is independent of the disease. Therefore, these markers can serve to indicate whether a particular course of treatment is effective in lessening a disease state or disorder.

10   Surrogate markers are of particular use when the presence or extent of a disease state or disorder is difficult to assess through standard methodologies (e.g., early stage tumors), or when an assessment of disease progression is desired before a potentially dangerous clinical endpoint is reached (e.g., an assessment of cardiovascular disease can be made using cholesterol levels as a surrogate marker, and an analysis of HIV infection can be made using

15   HIV RNA levels as a surrogate marker, well in advance of the undesirable clinical outcomes of myocardial infarction or fully-developed AIDS). Examples of the use of surrogate markers have been described (e.g., Koomen et al., 2000, J. Mass. Spectrom. 35:258-264; James, 1994, AIDS Treat. News Arch. 209).

[0284]   The 22437 molecules of the invention are also useful as pharmacodynamic markers.

20   As used herein, a "pharmacodynamic marker" is an objective biochemical marker which correlates specifically with drug effects. The presence or quantity of a pharmacodynamic marker is not related to the disease state or disorder for which the drug is being administered; therefore, the presence or quantity of the marker is indicative of the presence or activity of the drug in a subject. For example, a pharmacodynamic marker can be indicative of the

25   concentration of the drug in a biological tissue, in that the marker is either expressed or transcribed or not expressed or transcribed in that tissue in relationship to the level of the drug. In this fashion, the distribution or uptake of the drug can be monitored by the pharmacodynamic marker. Similarly, the presence or quantity of the pharmacodynamic marker can be related to the presence or quantity of the metabolic product of a drug, such that the

30   presence or quantity of the marker is indicative of the relative breakdown rate of the drug in

vivo. Pharmacodynamic markers are of particular use in increasing the sensitivity of detection of drug effects, particularly when the drug is administered in low doses. Since even a small amount of a drug can be sufficient to activate multiple rounds of marker (e.g., a 22437 marker) transcription or expression, the amplified marker can be in a quantity which is more readily

5   detectable than the drug itself. Also, the marker can be more easily detected due to the nature of the marker itself; for example, using the methods described herein, anti-22437 antibodies can be employed in an immune-based detection system for a 22437 protein marker, or 22437-specific radiolabeled probes can be used to detect a 22437 mRNA marker. Furthermore, the use of a pharmacodynamic marker can offer mechanism-based prediction of risk due to drug

10   treatment beyond the range of possible direct observations. Examples of the use of pharmacodynamic markers have been described (e.g., U.S. Patent number 6,033,862; Hattis et al., 1991, Env. Health Perspect. 90: 229-238; Schentag, 1999, Am. J. Health-Syst. Pharm. 56 Suppl. 3: S21-S24; Nicolau, 1999, Am, J. Health-Syst. Pharm. 56 Suppl. 3: S16-S20).

[0285]   The 22437 molecules of the invention are also useful as pharmacogenomic markers.

15   As used herein, a "pharmacogenomic marker" is an objective biochemical marker which correlates with a specific clinical drug response or susceptibility in a subject (e.g., McLeod et al., 1999, Eur. J. Cancer 35:1650-1652). The presence or quantity of the pharmacogenomic marker is related to the predicted response of the subject to a specific drug or class of drugs prior to administration of the drug. By assessing the presence or quantity of one or more

20   pharmacogenomic markers in a subject, a drug therapy which is most appropriate for the subject, or which is predicted to have a greater degree of success, can be selected. For example, based on the presence or quantity of RNA, or protein (e.g., 22437 protein or RNA) for specific tumor markers in a subject, a drug or course of treatment can be selected that is optimized for the treatment of the specific tumor likely to be present in the subject. Similarly, the presence or

25   absence of a specific sequence mutation in 22437 DNA can correlate 22437 drug response. The use of pharmacogenomic markers therefore permits the application of the most appropriate treatment for each subject without having to administer the therapy.

[0286]   Pharmaceutical Compositions

[0287]   The nucleic acid and polypeptides, fragments thereof, as well as anti-22437 antibodies (also referred to herein as "active compounds") of the invention can be incorporated into pharmaceutical compositions. Such compositions typically include the nucleic acid molecule, protein, or antibody and a pharmaceutically acceptable carrier. Similarly, compounds which modulate expression of the 22437 gene or activity of 22437 protein can be combined with a pharmaceutically acceptable carrier to form a pharmaceutical composition. As used herein the language "pharmaceutically acceptable carrier" includes solvents, dispersion media, coatings, antibacterial and antifungal agents, isotonic and absorption delaying agents, and the like, compatible with pharmaceutical administration. Supplementary active compounds can also be incorporated into the compositions.

[0288]   A pharmaceutical composition is formulated to be compatible with its intended route of administration. Examples of routes of administration include parenteral, e.g., intravenous, intradermal, subcutaneous, oral (e.g., inhalation), transdermal (topical), transmucosal, and rectal administration. Solutions or suspensions used for parenteral, intradermal, or subcutaneous application can include the following components: a sterile diluent such as water for injection, saline solution, fixed oils, polyethylene glycols, glycerine, propylene glycol or other synthetic solvents; anti-bacterial agents such as benzyl alcohol or methyl parabens; anti-oxidants such as ascorbic acid or sodium bisulfite; chelating agents such as ethylenediaminetetraacetic acid; buffers such as acetates, citrates or phosphates and agents for the adjustment of tonicity such as sodium chloride or dextrose. pH can be adjusted with acids or bases, such as hydrochloric acid or sodium hydroxide. The parenteral preparation can be enclosed in ampoules, disposable syringes, or multiple dose vials made of glass or plastic.

[0289]   Pharmaceutical compositions suitable for injectable use include sterile aqueous solutions (where water soluble) or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersion. For intravenous administration, suitable carriers include physiological saline, bacteriostatic water, Cremophor EL™ (BASF, Parsippany, NJ) or phosphate buffered saline (PBS). In all cases, the composition must be sterile and should be fluid to the extent that easy syringability exists. It should be stable under the conditions of manufacture and storage and must be preserved against the contaminating

- 71 -

action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyethylene glycol, and the like), and suitable mixtures thereof. The proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. Prevention of the action of microorganisms can be achieved by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, ascorbic acid, thimerosal, and the like. In many cases, it will be preferable to include isotonic agents, for example, sugars, polyalcohols such as mannitol, sorbitol, or sodium chloride in the composition. Prolonged absorption of the injectable compositions can be brought about by including an agent in the composition that delays absorption, for example, aluminum monostearate or gelatin.

[0290] Sterile injectable solutions can be prepared by incorporating the active compound in the required amount in an appropriate solvent with one or a combination of ingredients enumerated above, as required, followed by filter sterilization. Generally, dispersions are prepared by incorporating the active compound into a sterile vehicle that contains a basic dispersion medium and the other required ingredients from those enumerated above. In the case of sterile powders for the preparation of sterile injectable solutions, the preferred methods of preparation are vacuum drying and freeze-drying, which yield a powder comprising the active ingredient and any additional desired ingredient from a previously sterile filtered solution thereof.

[0291] Oral compositions generally include an inert diluent or an edible carrier. For the purpose of oral therapeutic administration, the active compound can be incorporated with excipients and used in the form of tablets, troches, or capsules, e.g., gelatin capsules. Oral compositions can also be prepared using a fluid carrier for use as a mouthwash. Pharmaceutically compatible binding agents and/or adjuvant materials can be included as part of the composition. The tablets, pills, capsules, troches and the like can contain any of the following ingredients, or compounds of a similar nature: a binder, such as microcrystalline cellulose, gum tragacanth or gelatin; an excipient, such as starch or lactose; a disintegrating agent, such as alginic acid, Primogel™, or corn starch; a lubricant, such as magnesium stearate

or Sterotes™; a glidant, such as colloidal silicon dioxide; a sweetening agent, such as sucrose or saccharin; or a flavoring agent, such as peppermint, methyl salicylate, or orange flavoring.

[0292]   For administration by inhalation, the compounds are delivered in the form of an aerosol spray from pressured container or dispenser that contains a suitable propellant, e.g., a gas such as carbon dioxide, or a nebulizer.

[0293]   Systemic administration can also be by transmucosal or transdermal means. For transmucosal or transdermal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art, and include, for example, for transmucosal administration, detergents, bile salts, and fusidic acid derivatives. Transmucosal administration can be accomplished using nasal sprays or suppositories. For transdermal administration, the active compounds are formulated into ointments, salves, gels, or creams as generally known in the art.

[0294]   The compounds can also be prepared in the form of suppositories (e.g., with conventional suppository bases such as cocoa butter and other glycerides) or retention enemas for rectal delivery.

[0295]   In one embodiment, the active compounds are prepared with carriers that will protect the compound against rapid elimination from the body, such as a controlled release formulation, including implants and microencapsulated delivery systems. Biodegradable, biocompatible polymers can be used, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters, and polylactic acid. Methods for preparation of such formulations will be apparent to those skilled in the art. The materials can also be obtained commercially from Alza Corporation and Nova Pharmaceuticals, Inc. Liposomal suspensions (including liposomes targeted to infected cells using monoclonal antibodies directed towards viral antigens) can also be used as pharmaceutically acceptable carriers. These can be prepared according to described methods (e.g., U.S. Patent number 4,522,811).

[0296]   It is advantageous to formulate oral or parenteral compositions in dosage unit form for ease of administration and uniformity of dosage. Dosage unit form as used herein refers to physically discrete units suited as unitary dosages for the subject to be treated; each unit containing a predetermined quantity of active compound calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier.

- 73 -

[0297]   Toxicity and therapeutic efficacy of such compounds can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., for determining the LD_{50} (the dose lethal to 50% of the population) and the ED_{50} (the dose therapeutically effective in 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index and it can be expressed as the ratio LD_{50}/ED_{50}. Compounds that exhibit high therapeutic indices are preferred. While compounds that exhibit toxic side effects can be used, care should be taken to design a delivery system that targets such compounds to the site of affected tissue in order to minimize potential damage to uninfected cells and, thereby, reduce side effects.

[0298]   The data obtained from the cell culture assays and animal studies can be used in formulating a range of dosage for use in humans. The dosage of such compounds lies preferably within a range of circulating concentrations that include the ED_{50} with little or no toxicity. The dosage can vary within this range depending upon the dosage form employed and the route of administration utilized. For any compound used in the method of the invention, the therapeutically effective dose can be estimated initially from cell culture assays. A dose can be formulated in animal models to achieve a circulating plasma concentration range that includes the IC_{50} (i.e., the concentration of the test compound which achieves a half-maximal inhibition of symptoms) as determined in cell culture. Such information can be used to more accurately determine useful doses in humans. Levels in plasma can be measured, for example, by high performance liquid chromatography.

[0299]   As defined herein, a therapeutically effective amount of protein or polypeptide (i.e., an effective dosage) ranges from about 0.001 to 30 milligrams per kilogram body weight, preferably about 0.01 to 25 milligrams per kilogram body weight, more preferably about 0.1 to 20 milligrams per kilogram body weight, and even more preferably about 1 to 10 milligrams per kilogram, 2 to 9 milligrams per kilogram, 3 to 8 milligrams per kilogram, 4 to 7 milligrams per kilogram, or 5 to 6 milligrams per kilogram body weight. The protein or polypeptide can be administered one time per week for between about 1 to 10 weeks, preferably between 2 to 8 weeks, more preferably between about 3 to 7 weeks, and even more preferably for about 4, 5, or 6 weeks. The skilled artisan will appreciate that certain factors can influence the dosage and timing required to effectively treat a subject, including but not limited to the severity of the

disease or disorder, previous treatments, the general health and/or age of the subject, and other diseases present. Moreover, treatment of a subject with a therapeutically effective amount of a protein, polypeptide, or antibody can include a single treatment or, preferably, can include a series of treatments.

5 **[0300]** For antibodies, the preferred dosage is 0.1 milligrams per kilogram of body weight (generally 10 to 20 milligrams per kilogram). If the antibody is to act in the brain, a dosage of 50 to 100 milligrams per kilogram is usually appropriate. Generally, partially human antibodies and fully human antibodies have a longer half-life within the human body than other antibodies. Accordingly, lower dosages and less frequent administration is often possible.

10 Modifications such as lipidation can be used to stabilize antibodies and to enhance uptake and tissue penetration (e.g., into the brain). A method for lipidating antibodies is described by Cruikshank et al. (1997, J. AIDS Hum. Retrovir. 14:193).

[0301] The present invention encompasses agents that modulate expression or activity of a 22437 protein or nucleic acid. An agent may, for example, be a small molecule. For example,

15 such small molecules include, but are not limited to, peptides, peptidomimetics (e.g., peptoids), amino acids, amino acid analogs, polynucleotides, polynucleotide analogs, nucleotides, nucleotide analogs, organic or inorganic compounds (i.e., including hetero-organic and organo-metallic compounds) having a molecular weight less than about 10,000 grams per mole, organic or inorganic compounds having a molecular weight less than about 5,000 grams per

20 mole, organic or inorganic compounds having a molecular weight less than about 1,000 grams per mole, organic or inorganic compounds having a molecular weight less than about 500 grams per mole, and salts, esters, and other pharmaceutically acceptable forms of such compounds.

[0302] Examples of suitable doses include milligram or microgram amounts of the small

25 molecule per kilogram of subject or sample weight (e.g., about 1 microgram per kilogram to about 500 milligrams per kilogram, about 100 micrograms per kilogram to about 5 milligrams per kilogram, or about 1 microgram per kilogram to about 50 micrograms per kilogram. It is furthermore understood that appropriate doses of a small molecule depend upon the potency of the small molecule with respect to the expression or activity to be modulated. When one or

30 more of these small molecules is to be administered to an animal (e.g., a human) in order to

modulate expression or activity of a polypeptide or nucleic acid of the invention, a physician, veterinarian, or researcher may, for example, prescribe a relatively low dose at first, subsequently increasing the dose until an appropriate response is obtained. In addition, it is understood that the specific dose level for any particular animal subject will depend upon a

5   variety of factors including the activity of the specific compound employed, the age, body weight, general health, gender, and diet of the subject, the time of administration, the route of administration, the rate of excretion, any drug combination, and the degree of expression or activity to be modulated.

[0303]   An antibody (or fragment thereof) can be conjugated to a therapeutic moiety such as

10   a cytotoxin, a therapeutic agent or a radioactive metal ion. A cytotoxin or cytotoxic agent includes any agent that is detrimental to cells. Examples include taxol, cytochalasin B, gramicidin D, ethidium bromide, emetine, mitomycin, etoposide, tenoposide, vincristine, vinblastine, colchicin, doxorubicin, daunorubicin, dihydroxy anthracin dione, mitoxantrone, mithramycin, actinomycin D, 1-dehydrotestosterone, glucocorticoids, procaine, tetracaine,

15   lidocaine, propranolol, and puromycin and analogs or homologs thereof. Therapeutic agents include, but are not limited to, antimetabolites (e.g., methotrexate, 6-mercaptopurine, 6-thioguanine, cytarabine, 5-fluorouracil decarbazine), alkylating agents (e.g., mechlorethamine, thioepa chlorambucil, melphalan, carmustine (BSNU) and lomustine (CCNU), cyclophosphamide, busulfan, dibromomannitol, streptozotocin, mitomycin C, and cis-

20   dichlorodiamine platinum (II) (DDP) cisplatin), anthracyclines (e.g., daunorubicin (formerly daunomycin) and doxorubicin), antibiotics (e.g., dactinomycin (formerly actinomycin), bleomycin, mithramycin, and anthramycin (AMC)), and anti-mitotic agents (e.g., vincristine and vinblastine).

[0304]   The conjugates of the invention can be used for modifying a given biological

25   response, and the drug moiety is not to be construed as limited to classical chemical therapeutic agents. For example, the drug moiety can be a protein or polypeptide possessing a desired biological activity. Such proteins can include, for example, a toxin such as abrin, ricin A, gelonin, pseudomonas exotoxin, or diphtheria toxin; a protein such as tumor necrosis factor, alpha-interferon, beta-interferon, nerve growth factor, platelet derived growth factor, tissue

30   plasminogen activator; or, biological response modifiers such as, for example, lymphokines,

- 76 -

interleukins-1, -2, and -6, granulocyte macrophage colony stimulating factor, granulocyte colony stimulating factor, or other growth factors.

[0305]   Alternatively, an antibody can be conjugated to a second antibody to form an antibody heteroconjugate as described by Segal in U.S. Patent number 4,676,980.

5   [0306]   The nucleic acid molecules of the invention can be inserted into vectors and used as gene therapy vectors. Gene therapy vectors can be delivered to a subject by, for example, intravenous injection, local administration (see U.S. Patent number 5,328,470) or by stereotactic injection (e.g., Chen et al., 1994, Proc. Natl. Acad. Sci. USA 91:3054-3057). The pharmaceutical preparation of the gene therapy vector can include the gene therapy vector in an

10   acceptable diluent, or can comprise a slow release matrix in which the gene delivery vehicle is imbedded. Alternatively, where the complete gene delivery vector can be produced intact from recombinant cells, e.g., retroviral vectors, the pharmaceutical preparation can include one or more cells which produce the gene delivery system.

[0307]   The pharmaceutical compositions can be included in a container, pack, or dispenser

15   together with instructions for administration.

[0308]   Methods of Treatment

[0309]   The present invention provides for both prophylactic and therapeutic methods of treating a subject at risk of (or susceptible to) a disorder or having a disorder associated with

20   aberrant or unwanted 22437 expression or activity. With regards to both prophylactic and therapeutic methods of treatment, such treatments can be specifically tailored or modified, based on knowledge obtained from the field of pharmacogenomics. "Pharmacogenomics," as used herein, refers to the application of genomics technologies such as gene sequencing, statistical genetics, and gene expression analysis to drugs in clinical development and on the

25   market. More specifically, the term refers the study of how a patient's genes determine his or her response to a drug (e.g., a patient's "drug response phenotype," or "drug response genotype".) Thus, another aspect of the invention provides methods for tailoring an individual's prophylactic or therapeutic treatment with either the 22437 molecules of the present invention or 22437 modulators according to that individual's drug response genotype.

30   Pharmacogenomics allows a clinician or physician to target prophylactic or therapeutic

treatments to patients who will most benefit from the treatment and to avoid treatment of patients who will experience toxic drug-related side effects.

[0310] Treatment is defined as the application or administration of a therapeutic agent to a patient, or application or administration of a therapeutic agent to an isolated tissue or cell line from a patient, who has a disease, a symptom of disease or a predisposition toward a disease, with the purpose to cure, heal, alleviate, relieve, alter, remedy, ameliorate, improve or affect the disease, the symptoms of disease or the predisposition toward disease.

[0311] A therapeutic agent includes, but is not limited to, small molecules, peptides, antibodies, ribozymes and antisense oligonucleotides.

[0312] In one aspect, the invention provides a method for preventing a disease or condition in a subject associated with an aberrant or unwanted 22437 expression or activity, by administering to the subject a 22437 or an agent which modulates 22437 expression, or at least one 22437 activity. Subjects at risk for a disease which is caused or contributed to by aberrant or unwanted 22437 expression or activity can be identified by, for example, any or a combination of diagnostic or prognostic assays as described herein. Administration of a prophylactic agent can occur prior to the manifestation of symptoms characteristic of the 22437 aberrance, such that a disease or disorder is prevented or, alternatively, delayed in its progression. Depending on the type of 22437 aberrance, for example, a 22437 protein, 22437 agonist or 22437 antagonist agent can be used for treating the subject. The appropriate agent can be determined based on screening assays described herein.

[0313] Expression of the 22437 gene is positively associated with the metastatic status of a tumor, and the ability of 22437 protein to catalyze degradation of extracellular matrices can promote growth and metastasis of tumors. Each of growth and metastasis of tumors can be inhibited by inhibiting either or both of 22437 gene expression and 22437 protein activity. Agents which can inhibit either 22437 gene expression or 22437 protein activity are preferably delivered in a tissue-specific manner, in order to minimize the effect of the agents on normal 22437 protein function in non-diseased tissues. Expression of the 22437 gene (and resulting activity of 22437 protein in cells in which it is expressed) can enhance neural cell growth (e.g., in cerebral astrocytes and other neurons) and can also enhance vascular endothelial proliferation and angiogenesis. Thus agents which enhance either or both of 22437 gene

expression and 22437 protein activity can be administered to sites at which one or more of vascular endothelial proliferation, angiogenesis, and neural cell growth are desired, such as at sites of traumatic wounds to soft tissues or ischemic damage (e.g., stroke-related cerebral ischemic damage) in order to promote healing or replacement of damaged tissue.

[0314] It is possible that some 22437 disorders can be caused, at least in part, by an abnormal level of gene product, or by the presence of a gene product exhibiting abnormal activity. As such, the reduction in the level and/or activity of such gene products would bring about the amelioration of disorder symptoms.

[0315] As discussed, successful treatment of 22437 disorders can be brought about by techniques that inhibit expression or activity of target gene products. For example, compounds, e.g., an agent identified using an assays described above, that proves to exhibit negative modulatory activity, can be used in accordance with the invention to prevent and/or ameliorate symptoms of 22437 disorders. Such molecules can include, but are not limited to peptides, phosphopeptides, small organic or inorganic molecules, or antibodies (including, for example, polyclonal, monoclonal, humanized, anti-idiotypic, chimeric or single chain antibodies, and Fab, F(ab')$_2$ and Fab expression library fragments, scFV molecules, and epitope-binding fragments thereof).

[0316] Further, antisense and ribozyme molecules that inhibit expression of the target gene can also be used in accordance with the invention to reduce the level of target gene expression, thus effectively reducing the level of target gene activity. Still further, triple helix molecules can be utilized in reducing the level of target gene activity. Antisense, ribozyme and triple helix molecules are discussed above.

[0317] It is possible that the use of antisense, ribozyme, and/or triple helix molecules to reduce or inhibit mutant gene expression can also reduce or inhibit the transcription (triple helix) and/or translation (antisense, ribozyme) of mRNA produced by normal target gene alleles, such that the concentration of normal target gene product present can be lower than is necessary for a normal phenotype. In such cases, nucleic acid molecules that encode and express target gene polypeptides exhibiting normal target gene activity can be introduced into cells via gene therapy method. Alternatively, in instances in that the target gene encodes an

extracellular protein, it can be preferable to co-administer normal target gene protein into the cell or tissue in order to maintain the requisite level of cellular or tissue target gene activity.

[0318]   Another method by which nucleic acid molecules can be utilized in treating or preventing a disease characterized by 22437 expression is through the use of aptamer molecules specific for 22437 protein. Aptamers are nucleic acid molecules having a tertiary structure that permits them to specifically bind to protein ligands (e.g., Osborne et al., 1997, Curr. Opin. Chem. Biol. 1:5-9; Patel, 1997, Curr. Opin. Chem. Biol. 1:32-46). Since nucleic acid molecules can in many cases be more conveniently introduced into target cells than therapeutic protein molecules can be, aptamers offer a method by which 22437 protein activity can be specifically decreased without the introduction of drugs or other molecules which can have pluripotent effects.

[0319]   Antibodies can be generated that are both specific for target gene product and that reduce target gene product activity. Such antibodies may, therefore, by administered in instances whereby negative modulatory techniques are appropriate for the treatment of 22437 disorders.

[0320]   In circumstances wherein injection of an animal or a human subject with a 22437 protein or epitope for stimulating antibody production is harmful to the subject, it is possible to generate an immune response against 22437 through the use of anti-idiotypic antibodies (e.g., Herlyn, 1999, Ann. Med. 31:66-78; Bhattacharya-Chatterjee et al., 1998, Cancer Treat. Res. 94:51-68). If an anti-idiotypic antibody is introduced into a mammal or human subject, it should stimulate the production of anti-anti-idiotypic antibodies, which should be specific to the 22437 protein. Vaccines directed to a disease characterized by 22437 expression can also be generated in this fashion.

[0321]   In instances where the target antigen is intracellular and whole antibodies are used, internalizing antibodies can be preferred. Lipofectin or liposomes can be used to deliver the antibody or a fragment of the Fab region that binds to the target antigen into cells. Where fragments of the antibody are used, the smallest inhibitory fragment that binds to the target antigen is preferred. For example, peptides having an amino acid sequence corresponding to the Fv region of the antibody can be used. Alternatively, single chain neutralizing antibodies that bind to intracellular target antigens can also be administered. Such single chain antibodies

can be administered, for example, by expressing nucleotide sequences encoding single-chain antibodies within the target cell population (e.g., Marasco et al., 1993, Proc. Natl. Acad. Sci. USA 90:7889-7893).

[0322] The identified compounds that inhibit target gene expression, synthesis and/or activity can be administered to a patient at therapeutically effective doses to prevent, treat or ameliorate 22437 disorders. A therapeutically effective dose refers to that amount of the compound sufficient to result in amelioration of symptoms of the disorders.

[0323] Toxicity and therapeutic efficacy of such compounds can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., for determining the LD_{50} (the dose lethal to 50% of the population) and the ED_{50} (the dose therapeutically effective in 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index and it can be expressed as the ratio LD_{50}/ED_{50}. Compounds that exhibit large therapeutic indices are preferred. While compounds that exhibit toxic side effects can be used, care should be taken to design a delivery system that targets such compounds to the site of affected tissue in order to minimize potential damage to uninfected cells and, thereby, reduce side effects.

[0324] The data obtained from the cell culture assays and animal studies can be used in formulating a range of dosage for use in humans. The dosage of such compounds lies preferably within a range of circulating concentrations that include the ED_{50} with little or no toxicity. The dosage can vary within this range depending upon the dosage form employed and the route of administration utilized. For any compound used in the method of the invention, the therapeutically effective dose can be estimated initially from cell culture assays. A dose can be formulated in animal models to achieve a circulating plasma concentration range that includes the IC_{50} (i.e., the concentration of the test compound that achieves a half-maximal inhibition of symptoms) as determined in cell culture. Such information can be used to more accurately determine useful doses in humans. Levels in plasma can be measured, for example, by high performance liquid chromatography.

[0325] Another example of determination of effective dose for an individual is the ability to directly assay levels of "free" and "bound" compound in the serum of the test subject. Such assays can utilize antibody mimics and/or "biosensors" that have been created through

- 81 -

molecular imprinting techniques. The compound which is able to modulate 22437 activity is used as a template, or "imprinting molecule," to spatially organize polymerizable monomers prior to their polymerization with catalytic reagents. The subsequent removal of the imprinted molecule leaves a polymer matrix that contains a repeated "negative image" of the compound

5   and is able to selectively rebind the molecule under biological assay conditions. Detailed reviews of this technique appear in the art (Ansell et al., 1996, Curr. Opin. Biotechnol. 7:89-94; Shea, 1994, Trends Polymer Sci. 2:166-173). Such "imprinted" affinity matrixes are amenable to ligand-binding assays, whereby the immobilized monoclonal antibody component is replaced by an appropriately imprinted matrix (e.g., a matrix described in Vlatakis et al., 1993, Nature

10   361:645-647. Through the use of isotope-labeling, the "free" concentration of compound which modulates the expression or activity of 22437 can be readily monitored and used in calculations of IC_{50}.

[0326]   Such "imprinted" affinity matrixes can also be designed to include fluorescent groups whose photon-emitting properties measurably change upon local and selective binding

15   of target compound. These changes can be readily assayed in real time using appropriate fiber optic devices, in turn allowing the dose in a test subject to be quickly optimized based on its individual IC_{50}. A rudimentary example of such a "biosensor" is discussed in Kriz et al. (1995, Anal. Chem. 67:2142-2144).

[0327]   Another aspect of the invention pertains to methods of modulating 22437 expression

20   or activity for therapeutic purposes. Accordingly, in an exemplary embodiment, the modulatory method of the invention involves contacting a cell with a 22437 or agent that modulates one or more of the activities of 22437 protein activity associated with the cell. An agent that modulates 22437 protein activity can be an agent as described herein, such as a nucleic acid or a protein, a naturally-occurring target molecule of a 22437 protein (e.g., a 22437

25   substrate or receptor), a 22437 antibody, a 22437 agonist or antagonist, a peptidomimetic of a 22437 agonist or antagonist, or other small molecule.

[0328]   In one embodiment, the agent stimulates one or more 22437 activities. Examples of such stimulatory agents include active 22437 protein and a nucleic acid molecule encoding 22437. In another embodiment, the agent inhibits one or more 22437 activities. Examples of

30   such inhibitory agents include antisense 22437 nucleic acid molecules, anti-22437 antibodies,

and 22437 inhibitors. These modulatory methods can be performed in vitro (e.g., by culturing the cell with the agent) or, alternatively, in vivo (e.g., by administering the agent to a subject). As such, the present invention provides methods of treating an individual afflicted with a disease or disorder characterized by aberrant or unwanted expression or activity of a 22437

5   protein or nucleic acid molecule. In one embodiment, the method involves administering an agent (e.g., an agent identified by a screening assay described herein), or combination of agents that modulates (e.g., up-regulates or down-regulates) 22437 expression or activity. In another embodiment, the method involves administering a 22437 protein or nucleic acid molecule as therapy to compensate for reduced, aberrant, or unwanted 22437 expression or activity.

10   **[0329]**   Stimulation of 22437 activity is desirable in situations in which 22437 is abnormally down-regulated and/or in which increased 22437 activity is likely to have a beneficial effect. For example, stimulation of 22437 activity is desirable in situations in which a 22437 is down-regulated and/or in which increased 22437 activity is likely to have a beneficial effect. Likewise, inhibition of 22437 activity is desirable in situations in which 22437 is abnormally

15   up-regulated and/or in which decreased 22437 activity is likely to have a beneficial effect.

[0330]   Pharmacogenomics

[0331]   The 22437 molecules of the present invention, as well as agents, or modulators which have a stimulatory or inhibitory effect on 22437 activity (e.g., 22437 gene expression) as

20   identified by a screening assay described herein can be administered to individuals to treat (prophylactically or therapeutically) 22437-associated disorders associated with aberrant or unwanted 22437 activity (e.g., disorders associated with aberrant sulfate metabolism or aberrant sulfatase activity). In conjunction with such treatment, pharmacogenomics (i.e., the study of the relationship between an individual's genotype and that individual's response to a

25   foreign compound or drug) can be considered. Differences in metabolism of therapeutics can lead to severe toxicity or therapeutic failure by altering the relation between dose and blood concentration of the pharmacologically active drug. Thus, a physician or clinician can consider applying knowledge obtained in relevant pharmacogenomics studies in determining whether to administer a 22437 molecule or 22437 modulator as well as tailoring the dosage and/or

30   therapeutic regimen of treatment with a 22437 molecule or 22437 modulator.

- 83 -

[0332] Pharmacogenomics deals with clinically significant hereditary variations in the response to drugs due to altered drug disposition and abnormal action in affected persons (e.g., Eichelbaum et al., 1996, Clin. Exp. Pharmacol. Physiol. 23:983-985; Linder et al., 1997, Clin. Chem. 43:254-266). In general, two types of pharmacogenetic conditions can be differentiated. Genetic conditions transmitted as a single factor altering the way drugs act on the body (altered drug action) or genetic conditions transmitted as single factors altering the way the body acts on drugs (altered drug metabolism). These pharmacogenetic conditions can occur either as rare genetic defects or as naturally-occurring polymorphisms. For example, glucose-6-phosphate dehydrogenase deficiency (G6PD) is a common inherited enzymopathy in which the main clinical complication is hemolysis after ingestion of oxidant drugs (anti-malarials, sulfonamides, analgesics, nitrofurans) and consumption of fava beans.

[0333] One pharmacogenomics approach to identifying genes that predict drug response, known as "a genome-wide association," relies primarily on a high-resolution map of the human genome consisting of already known gene-related markers (e.g., a "bi-allelic" gene marker map which consists of 60,000-100,000 polymorphic or variable sites on the human genome, each of which has two variants). Such a high-resolution genetic map can be compared to a map of the genome of each of a statistically significant number of patients taking part in a Phase II/III drug trial to identify markers associated with a particular observed drug response or side effect. Alternatively, such a high-resolution map can be generated from a combination of some ten million known single nucleotide polymorphisms (SNPs) in the human genome. As used herein, a "SNP" is a common alteration that occurs in a single nucleotide base in a stretch of DNA. For example, a SNP may occur once per every 1000 bases of DNA. A SNP can be involved in a disease process, however, the vast majority may not be disease-associated. Given a genetic map based on the occurrence of such SNPs, individuals can be grouped into genetic categories depending on a particular pattern of SNPs in their individual genome. In such a manner, treatment regimens can be tailored to groups of genetically similar individuals, taking into account traits that can be common among such genetically similar individuals.

[0334] Alternatively, a method termed the "candidate gene approach" can be utilized to identify genes that predict drug response. According to this method, if a gene that encodes a drug's target is known (e.g., a 22437 protein of the present invention), all common variants of

- 84 -

that gene can be fairly easily identified in the population and it can be determined if having one version of the gene versus another is associated with a particular drug response.

[0335]   Alternatively, a method termed "gene expression profiling," can be utilized to identify genes that predict drug response. For example, the gene expression of an animal dosed with a drug (e.g., a 22437 molecule or 22437 modulator of the present invention) can give an indication whether gene pathways related to toxicity have been turned on.

[0336]   Information generated from more than one of the above pharmacogenomics approaches can be used to determine appropriate dosage and treatment regimens for prophylactic or therapeutic treatment of an individual. This knowledge, when applied to dosing or drug selection, can avoid adverse reactions or therapeutic failure and thus enhance therapeutic or prophylactic efficiency when treating a subject with a 22437 molecule or 22437 modulator, such as a modulator identified by one of the exemplary screening assays described herein.

[0337]   The present invention further provides methods for identifying new agents, or combinations, that are based on identifying agents that modulate the activity of one or more of the gene products encoded by one or more of the 22437 genes of the present invention, wherein these products can be associated with resistance of the cells to a therapeutic agent. Specifically, the activity of the proteins encoded by the 22437 genes of the present invention can be used as a basis for identifying agents for overcoming agent resistance. By blocking the activity of one or more of the resistance proteins, target cells, e.g., cells of the immune system, will become sensitive to treatment with an agent that the unmodified target cells were resistant to.

[0338]   Monitoring the influence of agents (e.g., drugs) on the expression or activity of a 22437 protein can be applied in clinical trials. For example, the effectiveness of an agent determined by a screening assay as described herein to increase 22437 gene expression, protein levels, or up-regulate 22437 activity, can be monitored in clinical trials of subjects exhibiting decreased 22437 gene expression, protein levels, or down-regulated 22437 activity. Alternatively, the effectiveness of an agent determined by a screening assay to decrease 22437 gene expression, protein levels, or down-regulate 22437 activity, can be monitored in clinical trials of subjects exhibiting increased 22437 gene expression, protein levels, or up-regulated 22437 activity. In such clinical trials, the expression or activity of a 22437 gene, and

preferably, other genes that have been implicated in, for example, a 22437-associated disorder can be used as a "read out" or markers of the phenotype of a particular cell.

[0339] Other Embodiments

5 **[0340]** In another aspect, the invention features a method of analyzing a plurality of capture probes. The method can be used, e.g., to analyze gene expression. The method includes: providing a two-dimensional array having a plurality of addresses, each address of the plurality being positionally distinguishable from each other address of the plurality, and each address of the plurality having a unique capture probe, e.g., a nucleic acid or peptide sequence; contacting 10 the array with a 22437, preferably purified, nucleic acid, preferably purified, polypeptide, preferably purified, or antibody, and thereby evaluating the plurality of capture probes. Binding, e.g., in the case of a nucleic acid, hybridization with a capture probe at an address of the plurality, is detected, e.g., by signal generated from a label attached to the 22437 nucleic acid, polypeptide, or antibody.

15 **[0341]** The capture probes can be a set of nucleic acids from a selected sample, e.g., a sample of nucleic acids derived from a control or non-stimulated tissue or cell.

[0342] The method can include contacting the 22437 nucleic acid, polypeptide, or antibody with a first array having a plurality of capture probes and a second array having a different plurality of capture probes. The results of hybridization can be compared, e.g., to analyze 20 differences in expression between a first and second sample. The first plurality of capture probes can be from a control sample, e.g., a wild-type, normal, or non-diseased, non-stimulated, sample, e.g., a biological fluid, tissue, or cell sample. The second plurality of capture probes can be from an experimental sample, e.g., a mutant type, at risk, disease-state or disorder-state, or stimulated, sample, e.g., a biological fluid, tissue, or cell sample.

25 **[0343]** The plurality of capture probes can be a plurality of nucleic acid probes each of which specifically hybridizes, with an allele of 22437. Such methods can be used to diagnose a subject, e.g., to evaluate risk for a disease or disorder, to evaluate suitability of a selected treatment for a subject, to evaluate whether a subject has a disease or disorder. 22437 is associated with sulfate ester hydrolysis, thus it is useful for evaluating disorders relating to

- 86 -

aberrant sulfatase activity or to aberrant formation or hydrolysis of sulfate ester bonds, such as those disorders described herein.

[0344]   The method can be used to detect SNPs, as described above.

[0345]   In another aspect, the invention features, a method of analyzing a plurality of probes. The method is useful, e.g., for analyzing gene expression. The method includes: providing a two dimensional array having a plurality of addresses, each address of the plurality being positionally distinguishable from each other address of the plurality having a unique capture probe, e.g., wherein the capture probes are from a cell or subject which express 22437 or from a cell or subject in which a 22437 mediated response has been elicited, e.g., by contact of the cell with 22437 nucleic acid or protein, or administration to the cell or subject 22437 nucleic acid or protein; contacting the array with one or more inquiry probe, wherein an inquiry probe can be a nucleic acid, polypeptide, or antibody (which is preferably other than 22437 nucleic acid, polypeptide, or antibody); providing a two-dimensional array having a plurality of addresses, each address of the plurality being positionally distinguishable from each other address of the plurality, and each address of the plurality having a unique capture probe, e.g., wherein the capture probes are from a cell or subject which does not express 22437 (or does not express as highly as in the case of the 22437 positive plurality of capture probes) or from a cell or subject which in which a 22437 mediated response has not been elicited (or has been elicited to a lesser extent than in the first sample); contacting the array with one or more inquiry probes (which is preferably other than a 22437 nucleic acid, polypeptide, or antibody), and thereby evaluating the plurality of capture probes. Binding, e.g., in the case of a nucleic acid, hybridization with a capture probe at an address of the plurality, is detected, e.g., by signal generated from a label attached to the nucleic acid, polypeptide, or antibody.

[0346]   In another aspect, the invention features, a method of analyzing a plurality of probes or a sample. The method is useful, e.g., for analyzing gene expression. The method includes: providing a two dimensional array having a plurality of addresses, each address of the plurality being positionally distinguishable from each other address of the plurality having a unique capture probe, contacting the array with a first sample from a cell or subject which express or malexpress 22437 or from a cell or subject in which a 22437-mediated response has been elicited, e.g., by contact of the cell with 22437 nucleic acid or protein, or administration to the

cell or subject 22437 nucleic acid or protein; providing a two dimensional array having a plurality of addresses, each address of the plurality being positionally distinguishable from each other address of the plurality, and each address of the plurality having a unique capture probe, and contacting the array with a second sample from a cell or subject which does not express

5   22437 (or does not express as highly as in the case of the 22437 positive plurality of capture probes) or from a cell or subject which in which a 22437 mediated response has not been elicited (or has been elicited to a lesser extent than in the first sample); and comparing the binding of the first sample with the binding of the second sample. Binding, e.g., in the case of a nucleic acid, hybridization with a capture probe at an address of the plurality, is detected, e.g.,

10   by signal generated from a label attached to the nucleic acid, polypeptide, or antibody. The same array can be used for both samples or different arrays can be used. If different arrays are used the plurality of addresses with capture probes should be present on both arrays.

[0347]   In another aspect, the invention features a method of analyzing 22437, e.g., analyzing structure, function, or relatedness to other nucleic acid or amino acid sequences. The

15   method includes: providing a 22437 nucleic acid or amino acid sequence, e.g., nucleotide sequence from 22437 or a portion thereof; comparing the 22437 sequence with one or more preferably a plurality of sequences from a collection of sequences, e.g., a nucleic acid or protein sequence database; to thereby analyze 22437.

[0348]   The method can include evaluating the sequence identity between a 22437 sequence

20   and a database sequence. The method can be performed by accessing the database at a second site, e.g., via the internet.

[0349]   In another aspect, the invention features, a set of oligonucleotides, useful, e.g., for identifying SNPs, or identifying specific alleles of 22437. The set includes a plurality of oligonucleotides, each of which has a different nucleotide at an interrogation position, e.g., an

25   SNP or the site of a mutation. In a preferred embodiment, the plurality of oligonucleotides are identical in sequence with one another (except for differences in length). The oligonucleotides can be provided with differential labels, such that an oligonucleotide that hybridizes to one allele provides a signal that is distinguishable from an oligonucleotide that hybridizes to a second allele.

[0350]   The sequence of a 22437 molecules can be provided in a variety of media to facilitate use thereof. A sequence can be provided as a manufacture, other than an isolated nucleic acid or amino acid molecule, which contains sequence information for a 22437 nucleic acid or protein. Such a manufacture can provide a nucleotide or amino acid sequence, e.g., an open reading frame, in a form which allows examination of the manufacture using means not directly applicable to examining the nucleotide or amino acid sequences, or a subset thereof, as they exists in nature or in purified form.

[0351]   A 22437 nucleotide or amino acid sequence can be recorded on computer readable media. As used herein, "computer readable media" refers to any medium that can be read and accessed directly by a computer. Such media include, but are not limited to: magnetic storage media, such as floppy discs, hard disc storage media, and magnetic tape; optical storage media such as CD-ROM; electrical storage media such as RAM and ROM; and hybrids of these categories such as magnetic/optical storage media.

[0352]   A variety of data storage structures are available to a skilled artisan for creating a computer readable medium having recorded thereon a nucleotide or amino acid sequence of the present invention. The choice of the data storage structure will generally be based on the means chosen to access the stored information. In addition, a variety of data processor programs and formats can be used to store the nucleotide sequence information of the present invention on computer readable medium. The sequence information can be represented in a word processing text file, formatted in commercially-available software such as WordPerfect™ and Microsoft Word™, or represented in the form of an ASCII file, stored in a database application, such as DB2, Sybase™, Oracle™, or the like. The skilled artisan can readily adapt any number of data processor structuring formats (e.g., text file or database) in order to obtain computer readable medium having recorded thereon the nucleotide sequence information of the present invention.

[0353]   By providing the nucleotide or amino acid sequences of the invention in computer readable form, the skilled artisan can routinely access the sequence information for a variety of purposes. For example, one skilled in the art can use the nucleotide or amino acid sequences of the invention in computer readable form to compare a target sequence or target structural motif with the sequence information stored within the data storage means. A search is used to

- 89 -

identify fragments or regions of the sequences of the invention that match a particular target sequence or target motif.

[0354]   As used herein, a "target sequence" can be any DNA or amino acid sequence of six or more nucleotides or two or more amino acids. A skilled artisan can readily recognize that

5   the longer a target sequence is, the less likely a target sequence will be present as a random occurrence in the database. Typical sequence lengths of a target sequence are from about 10 to 100 amino acids or from about 30 to 300 nucleotide residues. However, it is well recognized that commercially important fragments, such as sequence fragments involved in gene expression and protein processing, can be of shorter length.

10   [0355]   Computer software is publicly available which allows a skilled artisan to access sequence information provided in a computer readable medium for analysis and comparison to other sequences. A variety of known algorithms are disclosed publicly and a variety of commercially available software for conducting search means are and can be used in the computer-based systems of the present invention. Examples of such software include, but are

15   not limited to, MacPattern (EMBL), BLASTN and BLASTX (NCBIA).

[0356]   Thus, the invention features a method of making a computer readable record of a sequence of a 22437 sequence that includes recording the sequence on a computer readable matrix. In a preferred embodiment, the record includes one or more of the following: identification of an open reading frame; identification of a domain, region, or site; identification

20   of the start of transcription; identification of the transcription terminator; the full length amino acid sequence of the protein, or a mature form thereof; the 5'- end of the translated region; or 5'- and/or 3'-regulatory regions.

[0357]   In another aspect, the invention features, a method of analyzing a sequence. The method includes: providing a 22437 sequence or record, in computer readable form; comparing

25   a second sequence to the gene name sequence; thereby analyzing a sequence. Comparison can include comparing to sequences for sequence identity or determining if one sequence is included within the other, e.g., determining if the 22437 sequence includes a sequence being compared. In a preferred embodiment, the 22437 or second sequence is stored on a first computer, e.g., at a first site and the comparison is performed, read, or recorded on a second

30   computer, e.g., at a second site. E.g., the 22437 or second sequence can be stored in a public or

proprietary database in one computer, and the results of the comparison performed, read, or recorded on a second computer. In a preferred embodiment the record includes one or more of the following: identification of an ORF; identification of a domain, region, or site; identification of the start of transcription; identification of the transcription terminator; the full

5   length amino acid sequence of the protein, or a mature form thereof; the 5'-end of the translated region; or 5'- and/or 3'-regulatory regions.

[0358]   This invention is further illustrated by the following examples that should not be construed as limiting. The contents of all references, patents and published patent applications cited throughout this application are incorporated herein by reference.

10

EXAMPLES

[0359]   Example 1

[0360]   Identification and Characterization of Human 22437 cDNA

[0361]   The human 22437 nucleotide sequence (Figure 1; SEQ ID NO: 1), which is

15   approximately 3513 nucleotides in length including non-translated regions, contains a predicted methionine-initiated coding sequence at about nucleotide residues 331-2940. The coding sequence encodes an 870 amino acid protein (SEQ ID NO: 2).

[0362]   Example 2

20   [0363]   Tissue Distribution of 22437 mRNA

[0364]   Northern blot hybridizations with various RNA samples can be performed under standard conditions and washed under stringent conditions, i.e., 0.2×SSC at 65°C. A DNA probe corresponding to all or a portion of the 22437 cDNA (SEQ ID NO: 1) can be used. The DNA can, for example, be radioactively labeled with ^{32}P-dCTP using the Prime-It™ Kit

25   (Stratagene, La Jolla, CA) according to the instructions of the supplier. Filters containing mRNA from mouse hematopoietic and endocrine tissues, and cancer cell lines (Clontech, Palo Alto, CA) can be probed in ExpressHyb™ hybridization solution (Clontech) and washed at high stringency according to manufacturer's recommendations.

[0365] Example 3

[0366] Recombinant Expression of 22437 in Bacterial Cells

[0367] In this example, 22437 is expressed as a recombinant glutathione-S-transferase (GST) fusion polypeptide in E. coli and the fusion polypeptide is isolated and characterized.

5 Specifically, 22437 nucleic acid sequences are fused to GST nucleic acid sequences and this fusion construct is expressed in E. coli, e.g., strain PEB199. Expression of the GST-22437 fusion construct in PEB199 is induced with IPTG. The recombinant fusion polypeptide is purified from crude bacterial lysates of the induced PEB199 strain by affinity chromatography on glutathione beads. Using polyacrylamide gel electrophoretic analysis of the polypeptide

10 purified from the bacterial lysates, the molecular weight of the resultant fusion polypeptide is determined.

[0368] Example 4

[0369] Expression of Recombinant 22437 Protein in COS Cells

15 **[0370]** To express the 22437 gene in COS cells, the pcDNA/Amp vector by Invitrogen Corporation (San Diego, CA) is used. This vector contains an SV40 origin of replication, an ampicillin resistance gene, an E. coli replication origin, a CMV promoter followed by a polylinker region, and an SV40 intron and polyadenylation site. A DNA fragment encoding the entire 22437 protein and an HA tag (Wilson et al., 1984, Cell 37:767) or a FLAG® tag fused

20 in-frame to its 3'-end of the fragment is cloned into the polylinker region of the vector, thereby placing the expression of the recombinant protein under the control of the CMV promoter.

[0371] To construct the plasmid, the 22437 DNA sequence is amplified by PCR using two primers. The 5' primer contains the restriction site of interest followed by approximately twenty nucleotides of the 22437 coding sequence starting from the initiation codon; the 3'-end

25 sequence contains complementary sequences to the other restriction site of interest, a translation stop codon, the HA tag or FLAG® tag and the last 20 nucleotides of the 22437 coding sequence. The PCR amplified fragment and the pcDNA/Amp vector are digested with the appropriate restriction enzymes and the vector is dephosphorylated using the CIAP enzyme (New England Biolabs, Beverly, MA). Preferably the two restriction sites chosen are different

30 so that the 22437 gene is inserted in the desired orientation. The ligation mixture is

transformed into E. coli cells (strains HB101, DH5alpha, SURE, available from Stratagene Cloning Systems, La Jolla, CA, can be used), the transformed culture is plated on ampicillin media plates, and resistant colonies are selected. Plasmid DNA is isolated from transformants and examined by restriction analysis for the presence of the correct fragment.

[0372] COS cells are subsequently transfected with the 22437-pcDNA/Amp plasmid DNA using the calcium phosphate or calcium chloride co-precipitation methods, DEAE-dextran-mediated transfection, lipofection, or electroporation. Other suitable methods for transfecting host cells can be found in Sambrook et al., (1989, Molecular Cloning: A Laboratory Manual. 2nd ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY). The expression of the 22437 polypeptide is detected by radiolabeling (^{35}S-methionine or ^{35}S-cysteine, available from NEN, Boston, MA, can be used) and immunoprecipitation (Harlow et al., 1988, Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY) using an HA-specific monoclonal antibody. Briefly, the cells are labeled for 8 hours with ^{35}S-methionine (or ^{35}S-cysteine). The culture media are then collected and the cells are lysed using detergents (RIPA buffer, 150 millimolar NaCl, 1% NP-40, 0.1% SDS, 0.5% DOC, 50 millimolar Tris, pH 7.5). Both the cell lysate and the culture media are precipitated with an HA-specific monoclonal antibody. Precipitated polypeptides are then analyzed by SDS-PAGE.

[0373] Alternatively, DNA containing the 22437 coding sequence is cloned directly into the polylinker of the pcDNA/Amp vector using the appropriate restriction sites. The resulting plasmid is transfected into COS cells in the manner described above, and the expression of the 22437 polypeptide is detected by radiolabeling and immunoprecipitation using a 22437-specific monoclonal antibody.

[0374] Example 5

[0375] Expression of the 22437 Gene

[0376] Expression of the 22437 gene was greater in cells obtained from ascites of humans afflicted with ovarian cancer than in normal human ovarian epithelial cells, as assessed both in gene expression array profiling experiments (results shown in Table 1) and in real time quantitative PCR amplification assays (results shown in Table 2; results were obtained using the TAQMAN® system using an ABI PRISM® 7700 instrument).

Table 1

Cell Type	Cell Designation	Relative Expression of the 22437 Gene
Normal Ovarian Epithelium	MDA 127	0.20
Normal Ovarian Epithelium	MDA 224	0.25
Normal Ovarian Epithelium	MDA223	0.14
Ovarian Cancer Ascites	MDA124	0.63
Ovarian Cancer Ascites	MDA 126	0.56

Table 2

Cell Type	Cell Designation	Relative Expression of the 22437 Gene
Normal Ovarian Epithelium	MDA 127	2.27
Normal Ovarian Epithelium	MDA 224	0.08
Ovarian Cancer Ascites	MDA 124	0.29
Ovarian Cancer Ascites	MDA 126	19.44

[0377]   Expression of the 22437 gene in cells of lung cancer cell lines that were grown on plastic and soft agar media was assessed in an array expression profiling experiment. The results of this experiment are shown in Table 3 and indicate that the 22437 gene is more highly expressed in cells grown in soft agar medium than in cells grown on plastic in the presence of an analogous liquid cell growth medium.

Table 3

Cell Line Type	Cell Line Designation	Growth Support Medium	Relative Expression of the 22437 Gene
Lung cancer	H460	Plastic	0.46
Lung cancer	H460	Soft agar	1.03
Lung cancer	H460_Incx	Plastic	0.56
Lung cancer	H460_Incx	Soft agar	1.19
Lung cancer	H460 p16	Plastic	0.48
Lung cancer	H460 p16	Soft agar	0.85

[0378] Table 4 displays the results of real time quantitative PCR (TAQMAN®) analysis of 22437 gene expression in cells of three breast cancer cell lines which were grown either in a soft agar medium or on plastic in the presence of an analogous liquid medium. As with the results obtained using lung cancer cell lines, higher expression of the 22437 gene was observed in ovarian cancer cells grown in semisolid (soft agar) medium than in ovarian cancer cells grown on plastic in the presence of an analogous liquid medium.

Table 4

Cell Line Type	Cell Line Designation	Growth Support Medium	Relative Expression of the 22437 Gene
Ovarian cancer	MCF3B	Plastic	1.45
Ovarian cancer	MCF3B	Soft Agar	11.31
Ovarian cancer	MCF10AT3B.cl5	Plastic	1.39
Ovarian cancer	MCF10AT3B.cl5	Soft Agar	12.00
Ovarian cancer	MCF10AT3B.cl6	Plastic	1.00
Ovarian cancer	MCF10AT3B.cl6	Soft Agar	38.32

[0379] Expression of the 22437 gene was also assessed in a selection of cell and tissue types by real time quantitative PCR (TAQMAN®) analysis. The data collected from individual TAQMAN® experiments are summarized in Tables 5-7. The data shown in Tables 5 and 6 were collected Relatively high levels of expression were observed in several normal tissues and cells, including brain cortex, astrocytes, cultured human umbilical vein endothelial cells (HUVEC), prostate epithelial cells, kidney, ovary, and skin. In diseased tissue samples, relatively high levels of 22437 gene expression were observed in glioblastoma, breast tumor, lung tumor, colon tumor, and skin decubitus. Increased 22437 expression was observed in a subset of breast, colon, lung, and ovarian xenograft cell lines (Table 7).

[0380] The results of in situ hybridization assays are listed in Table 8. Some tissue samples contained both normal tissue and tumor tissue, and both types of tissue were analyzed. Thus, some normal and tumor tissue samples in Table 8 have the same tissue designation. In Table 8, a minus sign ("-") indicates no 22437 expression was observed, a plus sign ("+") indicates detectable 22437 expression, and two plus signs ("++") indicates a higher degree of 22437 expression.

[0381]   Expression of the 22437 gene was compared in normal ovarian epithelium, ovarian cancer epithelium, inflammatory cells that had infiltrated ovarian tumors, and metastatic ovarian cancer epithelium. Expression of the 22437 gene was not detected in normal ovarian epithelium or in non-metastatic ovarian tumor epithelial cells. Limited expression of the gene was detected in metastatic ovarian tumor epithelial cells, and expression was also detected in inflammatory cells in metastatic and non-metastatic ovarian tumor epithelial cells.

[0382]   Expression of the 22437 gene was detected in 1 of 2 normal colon tissue samples, and was detected in all primary colon tumor samples. Expression of the gene was detected in colon tumor epithelial cells in 2 of 3 metastatic colon tumor epithelium samples that were tested, and expression of the gene was detected in inflammatory cells in the sample in the

metastatic colon tumor epithelium sample in which expression of the gene by colon tumor epithelial cells was not detected.

[0383]   Expression of the 22437 gene was not detected by in situ hybridization in the sole normal breast tissue sample that was assessed, but expression of the gene was detected in all three breast tumor samples that were assessed.

[0384]   Expression of the 22437 gene was not detected by in situ hybridization in any of three normal lung tissue or in any of five lung tumor samples that were assessed.

[0385]   Equivalents

[0386]   Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. Such equivalents are intended to be encompassed by the following claims.
